The air required for the oil burners is furnished by three Leiman positive pressure blowers, two of which have a capacity of 160 cu.ft. of free air per minute each, and the third a capacity of 360 cu.ft. When the furnace is in normal operation one large and one small blower are employed to supply the air. These discharge into a 4-in. steel main which is constricted at each burner to 3 in. in diameter.

Since the stoves could not be utilized to preheat the air furnished to the oil burners a preheater was built containing a coil of 60 ft. of 4-in. steel pipe heated by means of a small oil burner. During a furnace run pyrometers were located in the air main following the preheater, in the gas main leading from the dust catcher to the stoves, and in the flue leading from the stoves to the electric precipitator. The preheater is shown in the left foreground of Fig. 3.

MATERIALS USED

The phosphate used in these experiments consisted of "mine run" material furnished by the Cummer Lumber Co., of Jacksonville, from hard rock phosphate mines near Newberry, Fla. As pointed out in the previous report² on this process, the "mine run" phosphates from these deposits usually contain sufficient phosphate to admit of their furnace treatment without being reinforced with higher grade rock³—in fact, in most cases sand must be added in order to

FIG. FORMS OF BRIQUETS

obtain the proper silica-lime ratio (approximately 41 per cent CaO to 59 per cent SiO₂) to bring about the required reactions in the furnace. It has also been shown that these deposits contain considerable quantities of soft phosphate, a clay-like substance which acts as an excellent binder when the material is moistened and pressed into briquets. Such briquets will stand a drop of from 6 to 8 ft. upon a cement floor without shattering.

Two forms of briquets were used in the final experimental runs: The first in the shape of eggettes, 2 x 1½ x 1½ in., and the second in the form of pillows, 2 x 2 x 1½ in. The former shape has the advantage of having no sharp corners to sluff away, but the latter type does not pack so tightly in the furnace shaft and therefore allows a somewhat freer passage for the gases through the charge. While both forms of briquets worked quite satisfactorily in the furnace, showing no signs of cracking while being heated to

¹Loc. cit.

²The last batch of three tons of "mine run" phosphate, however, had to be reinforced with pebble phosphate.

a smelting temperature, the pillow form is preferable where the briquets do not have to be shipped or handled too frequently. The various types of briquets used during the development of this process are shown in Fig. 5.

experiments. This oil was purchased in barrel lots both from the Texas Co. and the Standard Oil Co. and varied from time to time in viscosity and specific gravity. The average weight per gal. was 7.5 lb. and the calorific value was in the neighborhood of 19,000 B.t.u. per lb., or 142,500 B.t.u. per gal. Either crude oil or the residuum of petroleum can be used and there appears to be no reason why powdered coal burners should not be employed where this fuel can be obtained at a lower cost than oil.

SUMMARY OF THE LAST TWO RUNS OF FURNACE

Since the completion of the present type of oil-burning furnace at Arlington Farm, Va., with its auxiliary equipment for the collection of phosphoric acid, at least six tests have been conducted in smelting briquetted charges of "run of mine" rock from the Florida phosphate fields. These tests were conducted for periods

Fig. 9. Generator, rectifier and transformer current.

The use of a briquetted charge was adopted in using the "mine run" phosphates of Florida for two reasons: First, the finely divided condition of these phosphates renders it essential to nodulize or briquet them before they can be handled in a plant of the blast-furnace type; and second, the necessity of maintaining reducing conditions until the mass has reached a smelting temperature. The latter requirement can be effectually fulfilled by incorporating coke in the briquetted charge.

The chemical composition of the briquets is shown in Table I.

Crude oil was used as the heating agent in these

of from six to twenty hours and the amounts of briquetted material charged ranged from 500 lb. to 1½ tons. While valuable data were obtained in practically all of these experimental runs, the furnace was in every instance except the last closed down before it was working at its maximum efficiency. In most cases the experiments were discontinued because of mechanical difficulties, which, however, were largely overcome in the last two tests. Only these last two runs therefore are recorded below.

At 8 a.m. on Oct. 6, 1920, the oil burners of the furnace were started and the first charge (50 lb.) of

briquetted material was added at 10:45 a.m., when the furnace shaft was nearly full of coke and the air supply to the oil burners preheated to a temperature of 210 deg. C. The first charge was followed at intervals of from ten to fifteen minutes by additional charges of from 50 to 200 lb. of briquets, till at 12:30 p.m., 1½ hours later, a total of 650 lb. had been added. At this time the temperature of the air to the oil burners was 260 deg. C. and the fumes of phosphoric acid were being copiously evolved. The furnace shaft being then four-fifths full, the top was closed down, the exhaust fan started, and the current turned into the electrical precipitator. Twenty-five minutes later the acid was dripping from the basin below the precipitator pipes, the first half gallon being collected in thirty-five minutes and having a concentration of 15 per cent H_3PO_4 . The exhaust fan used to draw the gas from the furnace, however, was not being run at sufficient speed to handle the volume of gas forced over from the furnace, so there was considerable back pressure at the stoves where the combustible gases were burned, which resulted in a large loss of phosphoric acid and caused the furnace to work rather irregularly.

At 1:20 p.m. 400 lb. more of briquetted charge was added and twenty minutes later the furnace was tapped. It was found that the entire charge had worked through to the hearth and the viscous nature of the slag made it difficult to withdraw the partly smelted product. By increasing the oil pressure and the volume of air to the burners, however, the slag was rendered considerably more molten and was finally removed. During the next three hours 850 lb. of briquets was added. The top of the furnace was then closed and the slag holes were automatically plugged by allowing successive waves of the molten slag to flow forward and freeze at these openings.

One hour later (5:20 p.m.) it was found that the entire charge (850 lb.) had completely worked through to the hearth, so 300 lb. more of briquets was added. At this time the air to the oil burners showed a temperature of 250 deg. C. and the gas entering the stoves showed a similar temperature—namely, 250 deg. C. The rate of consumption of the fuel at this time was only 9 gal. per hour for both burners. Twenty-five minutes later, or at 5:45 p.m., the last charge (300 lb.) was also found to have smelted and worked through to the furnace hearth.

No further material was added, and at 6:15 p.m., one-half hour later, an attempt was made to tap the furnace again, but owing to the fact that the slag had been allowed to accumulate and cool in the tap-holes it was found impossible to break through to the molten mass within. The slag being at the level of the oil burners, it was necessary to close down. The phosphoric acid was flowing from the precipitator at the rate of 1½ gal. an hour, but the concentration was only 21 per cent of H_3PO_4 . Analyses of the slag obtained after the furnace had cooled and was opened up showed a phosphoric acid content of from 7.99 to 13.63 per cent, or a volatilization of from 38 to 65.3 per cent of that originally in the charge.

The outstanding feature of this run was the rapid rate at which the material was reduced to a state of incipient fusion. No preparation was made to handle a large volume of slag in a limited time, and when this partly fused mass worked down through the furnace shaft, covering the slag already on the hearth, it seemed

to cool the latter to the point where the evolution of phosphoric acid was much retarded. An analysis of the last slag produced, however, or that upon the surface, showed that over 52 per cent of the phosphoric acid was apparently evolved while the charge was being reduced to a state of fusion. In this particular instance the evolution was at the rate of about 80.5 lb. of P_2O_5 per hour, with a fuel consumption of 9½ gal. of oil, giving a yield of approximately 8.5 lb. of P_2O_5 per gal. of oil. The present selling price of soluble phosphoric acid for fertilizer purposes is 6½c. per lb. The price of fuel oil in the Florida phosphate fields is in the neighborhood of 5c. per gal., so on this basis the cost of the fuel was 9.4 per cent of the value of the product. It was unfortunate that the furnace had to be closed down just at the time when it was heated to about the proper temperature to cause more rapid and complete evolution of the phosphoric acid, as a more protracted run would undoubtedly have yielded further valuable data. The highest temperature observed on the furnace during this run was about 1,500 deg. C., but no readings were made when the system was closed down.

THE SECOND TEST

Before undertaking the next test the throat of the furnace charge chamber was constricted from 12 to 9 in. in diameter in order to keep the charge from working down upon the hearth too rapidly. In addition to this a column or solid platform of carborundum brick was built under the mouth of this charge chamber to support the partly fused material being discharged therefrom and prevent its dropping directly into the more molten slag. The speed of the exhaust fan used in sucking the evolved gases through the stoves and precipitator was also increased so that the velocity of these gases in the 6-in. precipitator pipes reached seven linear feet per second. Since the precipitator was originally built to handle the phosphoric acid from an electric furnace where the velocity of the gases did not exceed three linear feet per second, it was expected that this increase in speed would result in a great loss of P_2O_5 .

This last experiment was begun at 8:30 a.m. on Oct. 28, after having heated up the furnace the previous day with a charge of coke. The first charge of 100 lb. of briquets was added at noon and twenty minutes later phosphoric acid was being copiously evolved. This charge was followed by others of from 100 to 200 lb. each at intervals of from ten minutes to one-half hour until at 2:15 p.m. 600 lb. had been charged. The furnace top was then closed and the exhaust fan started. At this time the air to the oil burners showed a temperature of 240 deg. C.,

Fifteen minutes later, or at 2:30 p.m., the current was turned into the electrical precipitator and here trouble developed almost immediately. It was found that one of the precipitator pipes was so badly buckled that it was impossible to center the wire sufficiently well to prevent the current from arcing across to the side. In spite of the fact that the precipitator was working only intermittently a small stream of acid was flowing from the basin within fifteen minutes. At 3 o'clock, however, it was decided to shut off the precipitator entirely, as the trouble grew steadily worse. The furnace was tapped for the first time at 3 p.m. and owing to the difficulty experienced in removing the slag and residual coke the tap-holes were left open until

4:20 p.m., or one and one-half hours. During this time 800 lb. more of briquetted charge was added. The average slag obtained from this first tap showed a content of 10.72 per cent P_2O_5 , or a volatilization of only 52.0 per cent of that originally present. A sample of more liquid slag dripping from the charge chamber upon the hearth and withdrawn from the furnace just before the tap-holes were closed showed also a content of 10.72 per cent P_2O_5 .

This seems to bear out the conclusions reached in the first tests that approximately one-half of the phosphoric acid was evolved quite rapidly during the fusion of the mass. At 5:35 p.m. 150 lb. more of briquets was added, making a total of 950 lb. since the tapping of the furnace was begun. The furnace top was closed down and the gas again passed through the precipitator. Apparently the charge worked down to the furnace hearth quite rapidly, for at 6 p.m., when an analysis was made of these gases, they showed only 1.20 per cent of PH_3 and 4 per cent of CO. These gases were not sufficiently combustible to burn at the stoves.

At 6:30 p.m. the furnace was again tapped. The slag was also similar to that obtained in the first instance, but showed upon analysis 12.08 per cent of P_2O_5 , or a volatilization of only 45.03 per cent. Both the furnace top and slag holes were left open until 9:30 p.m., during which time 600 lb. of material was charged and the temperature of the air supplying the oil burners rose to 350 deg. C. At this time it was decided to cut out the faulty pipe in the electrical precipitator. This, of course, resulted in increasing the velocity of the gases in the remaining five pipes to 8.4 linear feet per second, but the precipitation of acid was much improved. The slag holes were then closed, the top of the furnace was lowered, and at 9:45 p.m. the current was again thrown on the precipitator.

While this apparatus was unable to collect more than one-third of the P_2O_5 passing through it, a stream of dilute acid was soon flowing from the basin below the pipes at the rate of $\frac{1}{2}$ gal. in eighteen minutes. The concentration of the acid collected steadily rose as the temperature of the gases from the stoves increased from 100 to 145 deg. C. The first bottle ($\frac{1}{2}$ gal.) showed a concentration of 19.28 per cent H_3PO_4 ; the second bottle 21.5 per cent; the third 21 per cent; the fourth 23 per cent; the fifth 31 per cent; the sixth 41 per cent; and the seventh 60 per cent. The last runnings showed a concentration of 64 per cent H_3PO_4 . Had it been possible to continue the test longer the strength of the acid would no doubt have reached 80 to 90 per cent.

No more briquets were added until 11:10 p.m., when it was found that the charge chamber was completely empty. Then 400 lb. was added, but it ran through to the hearth almost immediately. At this time the temperature of the air to the oil burners had dropped to 325 deg. C., but the temperature of the gases to the stoves had risen to 300 deg. C., showing that there was practically no green charge in the shaft to absorb the heat units from the gases. On analysis these volatile products showed only about 6 $\frac{1}{2}$ per cent of combustible gases, exclusive of the phosphorus. This quantity was insufficient to cause the gases to burn. One hour later, however, it seemed apparent that the furnace was operating at its highest efficiency and therefore it was decided to charge all of the remaining briquets and fill the furnace shaft to the flue. Accordingly 950 lb.

was added between 12:15 a.m. and 1:14 a.m., Oct. 29. Fifteen minutes after the last addition of briquets the gases from the furnace were analyzed and showed the following composition:

	Per Cent		Per Cent
PH_3	2.2	O_2	0.2
CO	7.7	CO	13.8

These gases were able to support combustion and burned quietly at the stoves, increasing the temperature of the P_2O_5 going to the precipitator and also the strength of the acid collected. It was found at this time that the oil pressure, and therefore the amount consumed, could also be considerably lowered without cooling the furnace, and the rate of consumption was

TABLE II. PHOSPHORIC ACID CONTENT OF FINAL SLAG PRODUCED IN FURNACE RUN AND PERCENTAGE OF VOLATILIZATION OBTAINED

Sample No.	Description of Slag	Content of P_2O_5 Per Cent	Amount of P_2O_5 Volatilized Per Cent
4d	Bluish black, very glassy (1st runnings)	0.56	97.75
5d	Dark gray to green, very glassy (2nd runnings)	0.76	96.95
6d	Dark gray to green, very glassy (last runnings)	1.00	96.00
Average slag...		0.77	96.90

finally reduced to 8.3 gal. per hour for both burners. The furnace was allowed to run until 4 a.m., when it was again tapped and this time a very molten slag was obtained which continued to flow from the furnace in a steady stream for about one-half hour. Upon cooling this slag exhibited the characteristics of a brittle glass and ranged in color from grayish green to dark blue. Analysis of average samples of this slag are shown in Table II.

The average phosphoric acid content of this final slag, as will be noted, was 0.77 per cent, which means that nearly 97 per cent of the acid present in the original charge was volatilized. This elimination of acid from the slag is about as complete as that obtained by the use of the electric furnace for the same purpose.

YIELD AND COST OF PRODUCT

It is rather difficult to arrive at a fair figure showing the yield of acid (P_2O_5) per gal. of fuel oil consumed in a test of such short duration, particularly when the furnace was not functioning at its best until the latter part of the run. It seems fair, however, to take the rate of fuel consumption during the last two hours of the run, when the furnace attained its maximum temperature (between 1,500 and 1,600 deg. C.) as that at which the oil could be fed to the burners had it been possible to conduct the experiment for a longer period. During the last 3 $\frac{1}{2}$ hours of the test 950 lb. of briquets was charged into the furnace shaft and completely reduced to a molten slag with the evolution of 161.9 lb. of phosphoric acid (P_2O_5), or 96.90 per cent of that present in the original mass. The amount of oil consumed (at the rate of 8.3 gal. per hour) in driving off this acid was 29.15 gal. This gives a yield of 5.56 lb. of P_2O_5 per gal. of fuel. At the present price of oil and phosphoric acid given above the cost of the fuel consumed was 14.4 per cent of the value of the product for fertilizer purposes. It will be noticed, however, that the cost of fuel per lb. of acid produced appears actually higher than that obtained in the previous furnace run when the volatilization of acid was

much less complete. Probably better figures would have been obtained had the furnace been tapped earlier, as the acid may have been largely eliminated from the slag long before the latter was run out of the furnace. There is certainly little doubt, however, that in a prolonged test with a larger furnace a much lower fuel consumption per lb. of acid produced would result.

Yet even on the basis of these figures this process appears economically superior to the present method of producing soluble phosphates for fertilizer purposes. In manufacturing acid phosphate, for instance, sulphuric acid is used as the reagent and the cost of this

TABLE III. AMOUNTS AND COST OF MINE RUN PHOSPHATE AND COKE BREEZE REQUIRED PER TON OF PHOSPHORIC ACID, AND COST OF BRIQUETTING THIS MIXTURE FOR FURNACE TREATMENT

Charge and Its Manipulation for Furnace Treatment	Quantity Lb.	-Cost per Ton of Material	per Ton of P_2O_5
Mine run phosphate and sand	10,542		
Mining	10,542	\$1.00	\$4.70
Drying	10,542	0.50	2.35
Grinding	10,542	0.50	2.35
Coke breeze	1,438	8.00	5.14
Grinding	1,438	0.50	0.32
Mixing and briquetting	11,990	1.25	0.69
Total			11.75

acid represents at least 23 per cent of the value of the product. In the furnace process, on the other hand, fuel oil is the reagent used and even with the small and admittedly inefficient experimental plant the cost of fuel oil required to bring about the desired reactions was less than 15 per cent of the value of the product. To the cost of the fuel oil there must also be added, however, the price of the coke incorporated in the briquets, but this does not appreciably increase the expense of treatment.

In Table III the estimated cost of preparing the briquetted charge for furnace treatment is given, and in Table IV is shown the approximate cost of producing phosphoric acid by the furnace process in a plant

TABLE IV. COST PER TON OF PHOSPHORIC ACID (P_2O_5) 90 PER CENT YIELD, PRODUCED BY SMELTING A "RUN OF MINE" PHOSPHATE IN AN OIL-BURNING FURNACE

Daily Output 30 Tons of P_2O_5	
Briquetted material	\$21.55
Fuel oil, 360 gal. @ 5c. per gal.	18.00
Power	3.50
Interest on \$75,000 @ 6 per cent.	0.41
Depreciation on \$75,000 @ 20 per cent.	1.37
Labor - 18 men at \$5 per day	3.00
Insurance	0.50
Overhead expenses	1.50
Total	\$49.83

capable of turning out thirty tons per day of twenty-four hours. While some of the cost items are based on the data gathered in the runs of the experimental furnace at Arlington, Va., others are estimated or based on estimates received on the cost of building a larger plant. This plant would comprise the furnace and auxiliary equipment, including the electric precipitator and also grinding and briquetting machinery, storage bins, a mixer, drier, etc. The costs are also based on the assumption that the plant would be located in the Florida phosphate fields.

Even in making the most liberal allowances for the various items of expense the total cost of manufacturing phosphoric acid by the furnace process amounts to only \$49.83 per ton, or 2.49c. per lb., as against the present selling price of 6.25c. per lb.

It is interesting to compare this cost with that of producing a ton of phosphoric acid in the form of acid

TABLE V. AVERAGE COST OF PHOSPHORIC ACID (P_2O_5) PER TON IN THE FORM OF ACID PHOSPHATE

Phosphate rock, 6,250 lb. @ \$7.60 per ton	\$21.75
Sulphuric acid, 6,250 lb. @ \$9.50 per ton	29.69
Shrinkage, 6,250 lb.	6.56
Labor	6.25
Power	5.00
Depreciation	2.50
Overhead, insurance, taxes	7.50
Total	\$81.25

phosphate. In Table V is shown the average cost of this commodity as given by three large manufacturers.

Under the most favorable conditions the present cost of producing phosphoric acid in the form of acid phosphate is \$81.25 per ton, or 4.6c. per lb. Many manufacturers claim their cost of production is considerably higher than this figure.

On the basis of the data so far obtained, therefore, the cost of manufacturing phosphoric acid by the furnace method should be little more than one-half of that of producing it by the sulphuric acid process. When we take into consideration also the facts that by using the smelting process a concentrated product would be obtained which can stand heavy transportation and handling charges and that the life of the phosphate deposits would be greatly prolonged because the waste of low-grade phosphates would be largely eliminated the future of this process appears very promising indeed.

Vanadium*

BY FRANK L. HESS

THE minerals of vanadium are the sulphide, patronite; the oxidation products, vanadinite, desclozite, dechenite, psittacinite and related minerals found in the oxidized parts of lead and copper veins, carnotite and roscoelite (a vanadium mica). It is also present in unknown form and small fractions of 1 per cent in ilmenite, some asphaltites and some iron ores, such as the minette ores of northeastern France and other iron ores of France.

Patronite, now the most important vanadium ore, furnishing probably two-thirds of the world's vanadium, is found at only one place, Minasragra, Peru, where it occurs in a single mass of asphaltic material with a roughly lenticular horizontal section in sedimentary rocks. The depth to which it extends is unknown. Carnotite is found in this country in flat-lying soft sandstone beds, as a deposit formed by the replacement of wood or other vegetable remains, now fossilized, and as material impregnating the sandstone. Roscoelite occurs as a thin flat vein and as an impregnation in flat-lying sandstone near Placerville and Vanadium, Col.

Many ilmenites, segregations from igneous rocks, carry a small fraction of 1 per cent of vanadium but have not yet been worked for vanadium.

IMPORTS

Vanadium ore imported during the last six months of 1918 amounted to 1,772,215 lb., valued at \$5,333. No separate record was kept prior to July, 1918.

*Advance sheets, Mineral Resources of the U. S., 1918.

The United States, as the largest steel-making nation, is the largest user of vanadium. England, Germany and France buy ferrovanadium from this country and also buy ores when possible.

The Minasragra deposit is owned by an American company, the American Vanadium Co., but of course the political control is wholly in the hands of Peru.

The exports from Peru and the production in the

APPROXIMATE WORLD'S PRODUCTION OF VANADIUM, 1912-1918

	Quantity (Short Tons)	Peru (ore)— Percentage of V ₂ O ₅	Vanadium Contained (Short Tons)	United States (ore and con- centrates) Vanadium Contained (Short Tons)
1912	3,048	45.00	758	300
1913	None			432
1914	14.5	45.00	4	452
1915	3,145	45.58	803	627
1916	3,448	40.00	772	460
1917	4,083	35.78	821	484
1918	2,183	19.10	234	276

United States since 1912 have been as shown in the accompanying table.

TECHNOLOGY

In a general way the sulphide patronite is roasted and fused with a soda salt to form sodium vanadate, which after extraction is smelted in an electric furnace to ferrovanadium carrying between 35 and 40 per cent of vanadium.

The vanadates of lead, copper and zinc are commonly fused with a soda salt, the lead separating as metal and the vanadium going into the slag as sodium vanadate, from which point the general process is the same as for patronite.

In the treatment of carnotite for radium, vanadium is separated as oxide or iron vanadate, which is reduced in the electric furnace to ferrovanadium.

Rosecolite-bearing sandstone is roasted with salt and pyrite, lixiviated, filter-pressed, the solution treated with a ferric salt to precipitate the vanadium, the precipitate filtered out, and the ferric vanadate smelted in an electric furnace to ferrovanadium.

Some asphaltite has been burned in Peru and the ash shipped to the United States for treatment, presumably by fusing with soda, and so on.

In smelting the minette ores of France, the vanadium is carried into the slag and is extracted from that.

USES

The one use that makes vanadium of large economic value is as a scavenger and alloy in steel. Added to steels in quantities of 0.25 to 1.50 per cent, it is said to remove occluded oxygen and nitrogen and also to combine with the steel. In the smaller quantities, it is said to give great toughness and is used in steels for automobile axles and other parts on which severe strains come, for locomotive tires and frames and in similar steels. The larger quantities are used in high-speed and other tool steels. Its use is now as standard as that of tungsten in high-speed steels. Small quantities of vanadium have been used in dyes and medicines, and still smaller quantities for other purposes.

In the manufacture of steel, efforts are now being made to use molybdenum as a toughener and titanium as a scavenger as substitutes for vanadium, but these substitutes are not common. Titanium has been used in cast steels, though not with entire success.

Active or Available Chlorine

By J. R. MACMILLAN*

Although the following notes may seem to cover the simplest form of chemistry, the writer has encountered some peculiar ideas concerning the principles involved.

The term "active" or "available" chlorine is used to define the chlorine in bleaching powder that has oxidizing power, to distinguish this from the chlorine present in the form of chlorides or chlorates. It is the usual practice in routine analysis of bleaching powder to determine the active chlorine and also the total chlorine present. The difference in percentage between the active and total chlorine is called chloride chlorine or inert chlorine. Thus good bleaching powder may test:

	Per Cent
Active chlorine	37.5
Total chlorine	38.1
Chloride chlorine	0.6

while decomposed bleaching powder may test

	Per Cent
Active	29.5
Total	36.5
Chloride	7.0

If bleaching powder could be made under ideal conditions, the percentage of active and total chlorine would be the same.

When bleaching powder is dissolved, however, the term "active" chlorine becomes somewhat of a misnomer, as the active principle then is the oxygen in the calcium hypochlorite. However, as two atoms of chlorine are required to react to place one atom of oxygen in calcium hypochlorite, the results, if this is understood, are expressed correctly either in terms of chlorine or oxygen. The same is true when chlorine is absorbed in alkaline solutions or in milk of lime. If conditions as to temperature and distribution of gas are properly maintained, all of the chlorine absorbed will be indicated by analyses to be "active," although only one-half of it will be present in the hypochlorite formed. For instance, consider the reactions

Thus a pound of chlorine gas is equivalent to a pound of active chlorine in bleaching powder.

If some of the chlorine present in the form of chloride, according to these reactions, can be removed from the solution, then it is possible to get an analytical result showing a higher percentage of "active" chlorine than the percentage of total chlorine present. This is possible because the oxidizing power of the solution is really what is determined, although it is expressed in terms of chlorine. This condition can be demonstrated by passing chlorine slowly into strong, well-cooled caustic soda solution of say 40 per cent strength, and filtering off the salt crystals that form.

These statements are offered with the hope that they may be of assistance to some, as the following opinions have been encountered a number of times: First, that when chlorine is absorbed in an alkaline solution, only one-half of it can be "active," because the other half forms chlorides; second, that since, in a properly prepared solution made from chlorine and an alkali, the percentages of active and total chlorine as determined are equal, while only one-half of the chlorine is present in the hypochlorite formed, an efficiency of 200 per cent is attained in some unexplained manner.

A careful study of the valences involved will indicate the fallacy of both of these views.

Process and Equipment for Refining Benzene Hydrocarbons

A Detailed Discussion of Benzene Washer Construction—Materials of Construction: Cast Iron; Wrought Iron, Riveted and Welded, Sectional Plates, and Lead—Design of Body—Types of Agitators

By A. THAU*

NEARLY all modern benzene works are now arranged so as to be able to supply pure or washed products complying with the trade specifications, and in the design of the benzene plants such perfection has been reached during recent years that the consumers are content to buy the finished products instead of taking the crudes and purifying them at their own plants.

The purifying of the benzene products is, with suitable plant and properly trained men in charge, not a difficult task; but the most troublesome piece of apparatus in a benzene plant is undoubtedly the washer, in which the products are brought into intimate contact with different washing mediums, the effect of which is to take up and remove certain impurities from the benzene hydrocarbons which would otherwise impair their purity.

WASHING LIGHT OIL DIRECT

The crude benzene hydrocarbons are transferred into the washer, consisting of a vertical cylindrical vessel which they fill to only such a height that ample room remains for the addition of the respective washing mediums. When the benzene industry was comparatively young, the crude benzene or light oil distilled off the wash oil in the first stage, having a strength of 55 to 65 per cent, was accumulated and treated directly in the washer. There are a number of plants at work yet practicing this old wasteful method, which causes a great loss of both benzene and washing acid. In all modern plants the light oil is redistilled and divided into two or more fractions. A comparatively great amount of residue is recovered at the same time, consisting mainly of wash oil and naphthalene, which, though not of great value in itself, facilitates the washing process considerably by its absence and is responsible for great economy by reduced acid consumption and benzene losses compared with the first-mentioned method.

INTERMITTENT REDISTILLING

The recently built, large benzene plants can, according to their working methods, be divided into two classes. In the one, forming the majority, the light oil is transferred into a retort still having the form of a large horizontal boiler, carrying in place of the dome a high fractionating column. The light oil is distilled and the products fractionated according to their boiling point, conducted to different collecting tanks and each fraction is washed and finally redistilled separately as soon as a sufficient quantity of the respective product has been accumulated. The light oil is by this method redistilled in an intermittent process, after the con-

clusion of which the residue, consisting of wash oil with naphthalene in solution, is transferred to a crystallizing pan, in which the naphthalene settles and the wash oil can be decanted off.

CONTINUOUS REDISTILLING

The above-mentioned second method in redistilling light oil owes its existence to the efforts to make the whole benzene plant a continuously working process. These efforts have so far been crowned with success that it has been possible to make the whole distilling of the crude products continuously working—that is, up to the point where they must be subjected to washing. In the continuous redistilling of the light oil by this method, two fractions are obtained, a larger one consisting of 90 per cent benzene and a smaller one consisting of those hydrocarbons which have a higher boiling point than benzene. The residue runs off continuously in a thin stream conducted into a crystallizing pan.

CONTINUOUS FRACTIONATING

Although it is not intended to go fully into detail in this article as to the comparative merits of these two methods, it may appear to be disadvantageous to obtain only two fractions, making a further fractionating during the final distillation compulsory. Some benzene plant constructors claim to be able to provide continuous working stills yielding any desired number of fractions, but even at its best, these fractions are so roughly separated that a further close fractionating will be necessary during the final distilling. A splitting up in more than two fractions makes a continuous working still rather complicated and requires very close attention in maintaining certain temperatures.

TWO FRACTIONS WHILE REDISTILLING

From a practical point of view, especially in consideration of the washing process, dividing into more than two fractions is not an advantage, particularly as even with a very close fractionating of the crude products in the intermittent process a further, though slight, fractionating during the finishing distillation cannot altogether be avoided. The division of the crude products into two fractions simplifies the plant in that only two store tanks for the intermediate products are required, while such a plant is at a disadvantage in being unable to allow the sale of crude toluene, xylene, solvent naphtha, heavy benzene, etc. The demand of those products in the crude state is, however, limited.

METHODS OF WASHING DIFFERENT FRACTIONS

Thus, in washing crude benzene hydrocarbons, there are, depending upon the arrangement of the plant, three different possibilities: 1. The light oil is washed

*Superintendent, Coke Works and Chemical Plants of the Oxelösund's Iron Works, Oxelösund, in Sweden.

without redistilling. 2. The light oil is redistilled intermittently and split up in a number of distinct fractions which differ from the finished products only in that they contain chemical and mechanical impurities. 3. The light oil is, in continuous working stills, redistilled and separated in two fractions—viz., 90 per cent benzene, and hydrocarbons with a higher boiling point than benzene. Of course by the arrangement of the plant according to the second method it is also possible to divide the products into two fractions as in the third method, although this is rarely done.

As already mentioned, the first of these methods, though still practiced in a few old plants, is antiquated and too wasteful to be worthy of further consideration in this connection.

WASHING PARTICULAR FRACTIONS

In a plant using method 2 or 3 there is the 90 per cent benzene to be treated by itself in the washer. The specific gravity of the crude benzene is about 0.88, that of the respective washing medium—viz., sulphuric acid, water and alkaline lye 1.8, 1.0 and 1.15 respectively. It is thus evident that a considerable difference exists between the specific gravity of benzene and the respective washing medium with which it is treated, and as in the washing of benzene not much heat is developed, the two fluids do not mix readily, but separate easily. The same remarks apply to the next fraction—viz., toluene—though the temperature when mixing the acid with the toluene is raised somewhat higher than in the case of benzene. Coming to the last separately obtained crude fraction, the solvent naphtha, such a heat is set up by the reaction of the acid and the lye upon the hydrocarbons that a temperature approaching the boiling point of water is frequently reached. Taking into consideration that, in the case of a liquid, specific gravity means density, it will be quite apparent that an increase of temperature considerably facilitates the mixing of the liquids and jeopardizes their separating after washing. These facts make the treatment of solvent naphtha in the washer difficult and wasteful. Solvent naphtha forms with acid and lye an intimate mixture which can justly be called an emulsion. Once an intimate contact is reached between solvent naphtha and acid or lye, its temperature is raised so much that a settling and draining of the washing medium can be effected only after the lapse of a considerable time, during which the contents of the washer have somewhat cooled down. It must, however, be understood that the difference in specific gravity between solvent naphtha and the respective washing medium is for practical purposes equally as great as in the case of benzene and the washing medium, the only difference being that the washing medium acts quickly upon benzene, generating little reactionary heat, while with solvent naphtha the action is much slower. The temperature, however, is raised to a much higher degree, thereby balancing the former difference in specific gravity (or, better expressed, density) and facilitating the formation of an emulsion which even when cooled down will not dissociate completely. The washing medium drained off the solvent naphtha contains thus always a great proportion of hydrocarbons, and this is mainly responsible for the great losses in treating this fraction, which amount to 30-40 per cent at its best, not taking into account the time spent, which, to obtain a fair separating after the washing, may cover even several days.

It will thus be readily understood that method 3, by

which only two fractions have to be treated, has its advantages as far as the washing is concerned, while greater attention must be paid to the final distilling to obtain the proper fractions. The care necessary to be taken thereby cannot be called a disadvantage, as it does not entail extra cost for heat or labor and with a little skill the fractions can be separated with equal precision as if they had been fractionated before.

By splitting the light oil in two fractions, benzene and heavy hydrocarbons, while redistilling it, the latter consist approximately two-thirds of toluene and xylene and one-third solvent naphtha and still heavier compounds. Naturally such a compound fraction is more easily and quickly washed than if the solvent naphtha were treated by itself, though I have not been able to get any evidence that the washing losses are proportionately smaller. From the amount of liquid hydrocarbons in both cases, I am inclined to believe that the losses of solvent naphtha are in both washing methods proportionately equal. It is thus apparent that too close fractionating in redistilling the light oil is not an advantage.

MEANS AND EFFECTS OF WASHING

Without going into detail as to the actions taking place between hydrocarbons and washing medium, it may be said that the acid precipitates the greatest part of the impurities, which coagulate to a tarry consistency while warm, and in the colder state become of a pitchy nature and may even form lumps if not withdrawn quickly. In the heavier hydrocarbons some of the impurities are polymerized and remain in solution. They are recovered as residue in the still after the liquid hydrocarbons are driven off and can be evaporated to any desired consistency by vacuum distillation, forming the slightly transparent cumaron resin.

A certain amount of acid is retained by the hydrocarbons in the washer, which would be detrimental to their further use and injure the apparatus in which they are subjected to final distillation. To neutralize these remains of acid the hydrocarbons are equally intimately mixed with an alkaline lye; caustic soda lye at a density of 1.15 is probably the best. Ordinary washing soda or milk of lime is applied in some plants for the same purpose. Washing soda has the disadvantage of greater bulk. Soda lyes have the advantages over milk of lime that a smaller quantity need be applied in proportion to the effect, that no stirring arrangements are required to keep the alkali in suspension and that the whole method of application is much cleaner and more easily controlled.

As it would be a waste of alkali to neutralize all the acid which remains mechanically mixed with the hydrocarbons, these receive a preliminary washing with water, which removes a great proportion of the acid, and only those particles which are intimately mixed with the hydrocarbons and held in close suspension need be neutralized afterward. By this intermediate washing with water, the consumption of alkali is reduced considerably, no excessive reactionary heat is created and boiling over of the contents in the washer is prevented.

RE-USING SULPHURIC ACID FOR WASHING

In many, perhaps in most, modern plants provision is made to run the sulphuric acid which may have been used for a second or third washing into a specially provided store tank, from which it can be transferred to

the benzene washer again for further use later on. Appealing as this arrangement may seem from an economic standpoint, it is of little use in practice and if employed is generally the cause of more bother than economy owing to the impurities obstructing the connecting pipes and settling in the collecting tank. As all the acid used for washing benzene hydrocarbons is in any case regenerated and worked up in the manufacture of sulphate of ammonia, it is better not to take any risks as to the possibility of being able to apply the once-used acid a second time.

ARRANGEMENT OF WASHING APPARATUS

As will be gathered from the foregoing remarks, the washing apparatus must be of suitable design to induce a very rapid mixing and intimate contact between hydrocarbons and the respective washing medium and also must facilitate an easy settlement and separation of the two fluids afterward.

The position of the washer in the benzene plant must be elevated so that the used acid, decanted off at the bottom outlet, can run by gravity to a regenerating plant and so that the washed hydrocarbons can, also by gravity, be transferred to the finishing still.

CAPACITY OF WASHER

The washer body consists of a vertical cylinder, and its capacity must be such as to be in direct proportion to that of the finishing still, or where the latter is much greater the washer capacity may be one-half or one-third that of the finishing still. In all cases the proportion to the capacity must be such that the washer can be emptied completely into the finishing still. As the latter cannot be filled to the top, some free space must be left above the surface of the liquid.

MATERIAL OF WASHER--CAST IRON

The washer is made either of cast or of wrought iron. If of the latter, it must be lead lined. The objection against cast iron is the great weight, making a very strong and substantial substructure necessary to carry the whole apparatus. The difference in weight between a good lead-lined wrought-iron washer and one of bare cast iron of 1½ to 2-in. thickness is, however, not so very large. The rule has been in recent years to employ bare cast iron of about 1½-in. thickness and use it till the effect of the acid makes itself felt by a number of irregular holes eaten in the shell. The washer is then lined with sheet lead of ½ to ¾-in. thickness fastened by cutting out pieces corresponding with the holes eaten in the shell. The cut-out pieces are then run full of lead, which fills the holes in the shell and gives the lining a hold in as many places as possible.

Even under most favorable conditions the difference in price between sheet lead and cast iron is so great that the writer has found it more economical to calk holes eaten through the shell with soft lead. After the apparatus gets too highly depreciated it is replaced. In the long run it is cheaper than lead lining it, unless one gets a casting with a number of bad sand holes.

WROUGHT IRON, RIVETED

A fabricated wrought-iron washer must be lead lined, otherwise the acid will dissolve the iron scale around the rivets,* which then become loose and leak almost

immediately. To enable the lining to be placed evenly into the shell, the rivets must be countersunk on the inside. Through numerous holes drilled into the shell, lead rivets are driven to which the lining is attached by burning while the rivets are knocked flat on the outside of the shell. As there is a great difference in the expansion coefficient of lead as compared with wrought iron, the iron expanding and contracting with temperature more than lead, the use of lead-lined wrought-iron receptacles cannot be recommended at all in cases where temperature variations are had as in a benzene washer.

WROUGHT IRON, WELDED

If wrought iron is employed as material for the washer shell, only a cylinder with autogenously welded seam should be selected for the purpose and this covered inside homogeneously with a coating of lead about ¼ in. thick. Such a washer is preferable, even compared with one of cast iron, but its price is several times higher. While in the case of wrought iron the shell can be made of one single length, there are generally two or three pieces flanged together in a cast-iron washer.

SECTIONAL PLATES, LINED

There is a method of constructing washers of wrought- or cast-iron sections with horizontal and vertical flanges. The edges of the corresponding lead sheets are caught between these flanges, which are then bolted together tightly. Such washers last just as long as homogeneously lead-covered ones, if the single sections do not have too large surface dimensions. However, the large number of joints inside the washer give acid and impurities places for lodging and thus make clean washing almost impossible.

LEAD LINING

With lead-lined washers, the trouble caused by expansion makes itself felt. The lead sheeting gradually loses its elasticity. If not fastened over an area greater than 12 sq.in., it begins to bulge and warp. Then after a short time it will crack just over the bulges. In exceptionally bad cases the whole lining has dropped to the bottom of the washer because it had not been fastened in a sufficient number of places or over the necessary area. This trouble is avoided with washers built in sections that are flanged and bolted in both directions as well as with homogeneously lead-covered ones, because cast iron does not expand and contract as much as wrought iron. Also, owing to the greater thickness of a cast-iron shell, it is quite obvious that a lead-lined cast-iron washer will last longer than a wrought-iron one.

TOP OF WASHER

The top of the washer ends in a flange to which a lid is bolted, on which in most cases the gear and bearing for the internal stirring arrangement are mounted. The lid is provided with several openings, one in the center through which the shaft of the stirrer is introduced, one manhole with loose removable lid for inspection and several pipe openings for the introduction of the benzene hydrocarbons, acid and alkali respectively.

SHAPE OF WASHER

The design of the washer, the shape of its bottom and in particular the stirring arrangements are briefly described by a number of sketches of which Fig. 1 shows the simplest form in use.

*EDITOR'S NOTE: American practice overcomes this difficulty by fusing the edges of the rivets and calked joints electrothermally. Oxide, to be sure, is included, but the acid is prevented from working under the rivet head.

This washer is built up of three cylindrical flanged sections of cast iron. To the top flange a lid is bolted, which supports on two bracket bearings a horizontal shaft with fast and loose pulley at the end. The driving shaft is geared by a pair of cog wheels at the center of the lid to the vertical stirrer shaft, which is suspended freely from the lid and supported by means of ball bearings. At the bottom end an ordinary propeller is keyed to the shaft so that it will agitate the contents of the washer when revolving. The bottom section of the washer tapers in funnel shape into an outlet branch with flange. The arrangement shown in Fig. 1 of supporting the washer by vertical columns or joints is rather an exception now. To make the bottom connections of the washer as short as possible and easily accessible, modern washers are provided with brackets on the shell which rest on a horizontal girder frame. This may be placed in a corner of the building so that three sides of the frame are supported by the walls of the building and the fourth by a column. The shape of the bottom shown in Fig. 1 has in its steep taper the disadvantage that the heavy solid impurities collect immediately above the bottom outlet. If the drain cock cannot be opened at once for any reason, these tars upon cooling set hard, and great difficulties are then experienced in removing the charge. However, this bottom is of ideal shape for separately drawing off water or lye without loss of benzene hydrocarbons.

The bottom of the majority of washers is now tapered much less. The practice of having an acid washer from which the benzene is transferred into a second one for washing with water and lye has been abandoned nearly everywhere.

PROPELLER AGITATOR

The stirring arrangement is the most vital part of these washers. It is not enough simply to impart motion to the liquids. Owing to their comparatively great difference in density, they dissociate quickly and in order to maintain them in intimate contact, a very effective mixing is necessary. The acid has a tendency to settle on the bottom and the hydrocarbons tend to form a distinct upper layer. The propeller drives the acid upward into the hydrocarbon zone, from which it settles in a finely divided state. Experience has proved that the contents of the washer revolve with the propeller and the mixing is not sufficiently violent. Some improvement has been obtained by mounting in addition a horizontal paddlewheel just above the bottom section, geared by means of cog wheels to the vertical propeller shaft. The paddlewheel breaks up the boundary between the two liquids and acts as a brake to the rotating

motion of the liquid in the washer. The disadvantage of such an arrangement is obvious in that the internal arrangement is not sufficiently accessible and cannot be oiled or greased.

TURBINE AGITATORS

A similar washer with wrought-iron cylindrical shell and cast-iron lid and bottom section is shown in Fig. 2. A vertical pipe is rigidly fixed in the center of the lid extending into the washer guiding the agitator shaft, which reaches down as close to the bottom as possible.

The peculiar turbine wheel-like shape of the agitator insures better mixing and the semi-spherical shape of the bottom enables the stirring wheel to be placed very close to the draining outlet. This design, however, has not always proved advantageous. In cases where a large amount of solid impurities has settled out, these impurities cannot be withdrawn entirely without an accompanying amount of hydrocarbons, which, being fluid, have a tendency to force themselves through from above, before the impurities deposited on the sides have had time to reach the outlet. In all other respects the washer resembles the one shown in Fig. 1.

DIFFERENT METHODS OF AGITATING

It has generally been observed that the tendency of the two liquids in the washer to separate is greater than the effect of any stirring arrangement to mix them. To get a better washing effect with the new type of washers it is not enough simply to stir the liquids but one must be pumped through the other. This is accomplished in one of two ways. The hydrocarbons are

FIG. 2 WROUGHT IRON WASHER WITH TURBINE STIRRER

pumped from the upper part of the washer and forced through the washing medium layer at the bottom, or the action is reversed and the washing medium is pumped from the bottom and forced into the upper zone through the hydrocarbons. In the former the benzene rises in finely divided drops to the top, in the latter the acid is sprayed through the benzene. In both cases an equally intense washing effect is obtained. As to the respective advantages and disadvantages of these washers, they appear to be about balanced. If the benzene is pumped from above through the acid, the pump rotor must be placed in the

bottom and rotate and rest continually in the acid, the corrosive effects of which are soon felt, especially if a guide bearing for the shaft is provided at the bottom. If the bottom cock gets obstructed with congealed impurities, then the impeller wheel gets obstructed by these deposits, which impair the effect so much that it

must be cleaned by hand. The advantage of the above type rests with the fact that small charges of hydrocarbons can be treated, as the washer need not necessarily be full.

Free from the above-mentioned disadvantages is the second group of washers, in which the impeller is placed in the upper zone so that it comes in contact only with the acid while rotating. The quantity of hydrocarbons treated each time must always be sufficient to immerse the impeller completely. For plants which treat benzene hydrocarbons in great bulk and always work with full charges, this latter type of washer is to be recommended.

UPWARD PROPELLING AGITATOR

A simple type of washer in which the benzene is forced through the respective washing medium is shown in Fig. 3A. To the agitator shaft there is attached by spokes and brackets an inverted conic frustum, within which there is fastened an Archimedean screw. By revolving the frustum, the washing medium is drawn up by the screw and discharged at the top, where it passes down through the hydrocarbons to be circulated again.

DOWNWARD PROPELLING AGITATOR

In the type represented in Fig. 3B the action is reversed. Otherwise the arrangement is identical with that shown in Fig. 3A. The conical frustum is narrow at the top and wide at the bottom. The screw inside is arranged so that the hydrocarbons are forced downward through the cylinder and dispersed through the washing medium at the bottom, rising outside of the cylinder to the top, an action which is continuous.

UPWARD PROPELLING AGITATOR

In the washer shown in Fig. 3C the frustum around the Archimedean screw is stationary. It is held by a number of brackets on the washer bottom so that a passageway is formed underneath the cylinder edge. In the deepest part of the tapered bottom section of the washer, just over the draining outlet, a guide bearing

FIG. 3. UPWARD AND DOWNWARD PROPELLING AGITATORS

is fixed in a star-shaped bracket, guiding the lower end of the vertical shaft. The washing medium is driven up through the middle cylinder by the screw and falls down through the hydrocarbons in the annular space between the inner cylinder and the washer shell. By reversing the drive of the stirrer the action can be reversed.

The design shown in Fig. 3C has been improved to cover the whole diameter of the washer with the stirrer as shown in Fig. 4. The inner cylinder does not extend completely down to the tapered bottom of the washer, but rests on a number of brackets projecting horizontally inside. Under these brackets the star-like impeller, keyed to the suspended vertical shaft, is arranged; its diameter corresponds with that of the washer inside. The blades of the impeller are twisted propeller-like underneath the internal cylinder, and the ends extending outside of this cylinder are shaped like ordinary fan

FIG. 4. COMBINED MIXING AND PROPELLING AGITATOR

blades. When revolving the shaft, the twisted inner portion of the impeller creates a suction inside the inner cylinder through which the hydrocarbons are forced down, and by leaving the cylinder at the bottom, passing through the washing medium, they are again effectively mixed by being agitated from the fan blades.

While in the types shown in Figs. 1 and 2 the contents of the washer are simply agitated, in Figs. 3A, B and C they are mixed by forcing the two zones through each other. In the latest designs of washers efforts have been made to combine both types to obtain the double effect. The first construction of this kind is shown in Fig. 4, where mechanical agitation is provided in addition to pumping.

TURBINE PUMP IN BOTTOM

In the most modern types of washers a specially constructed turbine impeller has been adopted which not only pumps the liquid upward or downward but also throws it out with centrifugal force divided in very fine streams. Such a washer is shown in Fig. 5 which at the same time gives a good design for the bottom. The impeller has the form of a pipe which broadens out trumpet-like at the bottom and is built similar to a turbine pump with fine openings at its periphery and slots in the upper face. The impeller casting is fastened to the driving shaft by keys going right through the bushes and shaft. The impeller casting is bored out and slides over a pivot protruding through the

washer bottom and fastened tightly by a tapered bolt with nut at the end. The pivot serves as a guide; the shaft with impeller casting does not rest upon it, but is suspended freely and held by a ball bearing placed in a collar in the centre of the washer lid. The hydrocarbons are sucked down through the central tube and with centrifugal force are sprayed out of the openings on the periphery while the surplus is thrown out of the slots on the face, insuring a very effective mixing. The unfavorable effect of the acid upon the pivot is obvious and it need hardly be mentioned that the fine slots in the impeller get easily obstructed, if the impurities are allowed to congeal in the bottom.

TURBINE PUMP IN UPPER PART

The best type of washer for the treatment of full charges is represented in Fig. 6. Under the lid of the washer a number of right angle brackets are fastened, holding the vertical suction pipe, which broadens out at the top trumpet-like and reaches down close to the deepest point of the washer. It is fixed rigidly and does not revolve. Over the upper end of the pipe a turbine pump impeller of corresponding diameter to that of the trumpet end of the suction pipe rotates.

FIG. 5. TURBINE IMPELLER AGITATOR AT BASE

Under the top bearing in the lid of the washer a second bearing is arranged in a projecting bush about half way between washer lid and impeller, serving as a guide to the short impeller shaft. By revolving the impeller the washing medium is drawn up through the fixed pipe and thrown with centrifugal force in a spray through the hydrocarbons.

The advantages of this latter type are too obvious to call for much comment. Owing to the short impeller shaft, it requires less power and does not get out of order easily. No movable parts are immersed in acid and with proper construction of the lid, the internal parts can be made readily accessible without entering the washer. By comparing Figs. 5 and 6 it will be

FIG. 6. TURBINE IMPELLER AGITATOR AT TOP

noted that the washer shown in Fig. 6 must be more than three-fourths full to immerse the impeller so as to obtain a washing effect. In Fig. 5 the washer need be only half full to immerse the top end of the impeller suction pipe.

AGITATING BY COMPRESSED AIR

Even at its best the placing of mechanical stirring or pumping devices inside the washer is disadvantageous. To make the interior of the washer accessible and safe for men to enter, it must be boiled out and ventilated a considerable time to insure the absence of poisonous vapors. Efforts have been made to construct washers in which all internal moving parts are obviated. The most obvious arrangement is the proper application of compressed air introduced into the washer in a great number of places. Though good mechanical washing can be obtained by this means, the direct application of compressed air for this purpose is not practicable, since the air gets carburetted and charged with benzene vapors while passing through the liquid. As a supplementary means, in cases of emergency, a compressed air connection to the bottom outlet pipe of the washer is, however, an advantage, should the outlet become obstructed or the internal stirring arrangement get out of order before washing is completed.

WASHER WITHOUT AGITATOR

A good suggestion for a washer without internal moving parts is shown in Fig. 7, where a T-piece is provided under the washer outlet. To one end of this T-piece a centrifugal pump is connected by means of a cock or valve, the delivery pipe of which is conducted into the top of the washer and leads into a perforated coil. This coil is led round the periphery of the washer and has cross branches leading spoke-like to the center of the washer. The pump, which must be of

ample capacity, draws the washing medium from the bottom and forces it into the top coil, where by means of the perforations a fine distribution is obtained, while an intimate mixing is effected in the pump itself. To the suction pipe of the pump a water supply is connected for priming, so that the rest of the mixture contained in the pump and pipes can be driven out by water after the washing is completed and the valve in the suction pipe closed. Trials with this arrangement have been very promising as far as efficiency and convenience go; the only difficulty experienced rests with the glands of the pump, which wear out rapidly by coming in contact with acid and alkalis respectively.

CONTINUOUS WASHERS

In the endeavor to make the complete benzene plants continuous from the wash oil entering to the point where the finished products run into the store tanks,

FIG. 7. WASHER WITH CENTRIFUGAL PUMP

continuously working washers had necessarily to be introduced. The designs so far tried have not given promising results. They have had to be discarded and at this stage it would serve no useful purpose to dwell upon their design.

BENZENE SEPARATOR

Under the washer there is generally an open catch box arranged with central partition not reaching quite down to the bottom, and in such a manner that the flow entering from the washer outlet is spread out in a flat stream so as to make the appearance of hydrocarbons visible at once. The catch box must be fitted with easily operated valves or cocks so that its outlets can be closed suddenly to recover any hydrocarbons which may have entered and are retained by the central partition.

French North African Phosphate Deposits

A recent discussion among the French North African phosphate-mining interests has brought out the statement that the total annual production of phosphates in Tunisia, Algeria and Morocco is susceptible of an increase to 5,000,000 tons, of which amount Tunis should produce 2,000,000 tons. The present deficiency, reports Consul Cookingham at Tunis, of output is attributed largely to scarcity of available labor and lack of transportation facilities.

Effect of Ultra-Violet Rays on the Eye*

BY DR. C. R. KINDALL†

Recently thirty men were viewing the demonstration of a new portable electric arc-welding outfit. A few hours later seventeen of the thirty men reported to the doctor for treatment. They were suffering from traumatic conjunctivitis. In two cases the pain was very severe and the symptoms were similar to those of iritis. Morphine had to be administered to afford relief from pain. Only two men of the thirty were not affected in some way from this exposure. These two men wore thick-lensed orange-colored glasses. Several of the men wore orange-colored glasses with thin lenses, but the latter were not heavy enough to afford protection against an exposure as long as took place. The distance of the eye from the arc also influences the possibility of injury. Conjunctivitis is an inflammation of the conjunctiva; the conjunctiva is the mucous membrane covering the inside of the eyelids and part of the eyeball. Traumatic conjunctivitis is caused by foreign bodies in the eye, exposure of the eyes to high winds, dust, smoke, intense light from electric arc lamps and from electric-welding apparatus. In the instance mentioned above, the inflammation was due to the ultra-violet rays. The ultra-violet rays lie beyond the violet rays in the spectrum and are invisible to the eye. In some cases the effect is so severe that, in addition to conjunctivitis, an inflammation of the skin similar to sunburn is produced.

The symptoms of conjunctivitis caused by intense light or by the ultra-violet rays are marked photophobia (abnormal intolerance to light), excessive secretion of tears, intense smarting of the lid, contraction of the pupil, sometimes swelling of the lid and small ulcers developing on the eyeball or cornea. Unless properly treated by a physician immediately, chronic inflammation of the conjunctiva, cornea, iris or retina, and possibly blindness, may result.

Under proper treatment most cases get well in a few days. All treatments should be under the direction of a physician. That usually advised is to place ice packs on the patient's eyes three or four times daily. The pack should be left on from fifteen minutes to an hour. The eyes should be irrigated with normal salt solution (a teaspoonful to a quart of sterile water) or a saturated solution of boric acid several times daily. If there is a discharge of pus, a few drops of a 25 per cent solution of argyrol or a 5 per cent solution of protargol should be placed in the eyes three to six times daily. The patient should be confined to a darkened room until his condition improves in order to avoid complications. These treatments will reduce the swelling, give the patient comfort, and prevent the development of chronic conjunctivitis. In severe cases it may be necessary to administer morphine to relieve the pain.

At every plant where electric arc-welding outfits are used there should be an adequate supply of glasses the lenses of which are made up of alternate layers of red and blue glass or orange glasses of sufficient thickness to protect the eyes from the effects of ultra-violet rays. There should also be on hand at the plant dispensary or hospital a supply of boric acid, sterilized water, ordinary table salt, argyrol and protargol for immediate use. As previously mentioned, all cases of traumatic conjunctivitis caused by exposure to bright light or ultra-violet rays should be treated under the direction of a physician.

The Fundamentals of the Electrolytic Diaphragm Cell*—II

Effect of Washing Diaphragms on Voltage and Current and Decomposition Efficiencies—Removal of Alkaline Earths From Brine—Use of Purified and Crude Brine Liquors†

BY HUGH KELSEA MOORE •

THERE has been a great deal said and written about the merits of this cell and that cell, but little has been said about the use and abuse of cells in general or cells of the same type.

It thus happens that the exponent of one make of cell can take data from a plant using his cell running under favorable conditions and compare this with data taken from a plant using his competitor's cell running under unfavorable conditions. Neither of these results gives the buyer the exact truth, though it may help to sell the product inasmuch as the purchaser may be fooled into accepting these statements as representative of what may be expected of different makes of cells, when in most cases differences in the results can be more than accounted for by methods of operation.

Suppose an exponent of one cell goes to a would-be purchaser of some cell and gives A the following line of talk: "Come and visit our plant at Y and look at our records. You will find these cells running in a voltage of 3.4 to 3.6, amperes 1,200, current efficiency 95 to 97 per cent, decomposition efficiency 52 per cent, average power efficiency of 63 per cent, age of diaphragm 280 days, life of carbons 16 to 18 months, etc.

"If you will go to town W you will find an installation of our competitor's cells. You will find this plant running with cells having a voltage ranging from 3.3 to 4.7, or at an average of 4 volts. The current efficiency varies from 97 per cent on some cells to 66 per cent on others. The current varies from 1,200 to 1,800 amp. with a power efficiency varying from 67 per cent to 29 per cent, averaging perhaps 48 per cent. The age of the diaphragm in this plant is eighty-four days and the life of the carbons four months."

With two statements before him like this he would undoubtedly take the cell represented by Plant Y, especially if he knew nothing about electrolytic cells and their operation. And yet he may be very far from the truth. Do you know that the method of operation in two installations of the same cell can and does make greater differences than those stated above? One plant may be able to run its installation with a non-varying current density at the cathode while another plant finds that owing to conditions of varying load on other parts of the line it cannot furnish a constant current. One operator may not see the necessity of purifying his brine, while another may. These conditions alone will make startling differences in the results obtained.

EFFECT OF WASHING ON VOLTAGE

To show this Fig. 7 is submitted with curves A, B and C. A is a cell run constantly at 1,200 amp. current, with purified brine and with the diaphragm washed with water for a period of twenty-four hours once every thirty

days. B is a cell running on purified brine, with amperage varying from 1,200 to 1,900. The varying voltages in this and C have been adjusted by means of a correction chart to 1,200 amp. In this case washings were made at the end of sixty-one days, at the end of ninety days and at the end of 113 days. Curve C is a case where a cell running on impure brine has been washed at the end of sixty-one days, ninety days and 115 days. Curves A and B are on cells of purified brine.

In curve C unpurified brine was used. In order that

FIG. 7. EFFECT OF WASHING ON VOLTAGE

there may be no misunderstanding in relation to the salt and brine, the following compositions are given and in considering curves 7A, B and C, you will consider that the brine does not vary from what is given here.

For example, let us take a salt which analyzes as follows:

	Per Cent		Per Cent
Insoluble matter	0.40	CaSO ₄	0.70
CaCl ₂	0.36	NaCl	98.54
MgCl ₂	Trace		100.00

With brine made up 2½ lb. to the gallon we get from the above:

	Grams per Liter		Grams per Liter
Insoluble matter	1.20	CaSO ₄	2.10
CaCl ₂	1.08	NaCl	285.62
MgCl ₂	Trace		
Total grams other than water per liter			290.00

After adding soda ash to about 1 per cent excess of the requirements, filtering and neutralizing with HCl, we get a solution of the following composition:

	Grams per Liter		Grams per Liter
Insoluble m:	None	CaSO ₄	Heavy trace
CaCl ₂	None	Na ₂ SO ₄	2.20
MgCl ₂	Trace	NaCl	286.76

Now let us see the results of feeding the above-mentioned impure brine to a cell and compare these with the results obtained from the purified brine.

It will be observed that in C the voltage rises to 3.6 at the end of ten days, while in A and B the voltage

*Read before the American Institute of Chemical Engineers, Montreal, June 28, 1920.

†For Part I see CHEM. & MET. ENG., vol. 23, No. 21, Nov. 24, 1920, p. 1011.

does not rise to 3.6 until thirty days. If now the cells running on purified brine are washed at the end of thirty days for twenty-four hours, with water, it will be found upon starting up the voltage will have dropped to somewhere between 3.3 and 3.4. In the case before you the voltage upon starting up was 3.3. If the cell is again washed at the end of another thirty days or less we will have a similar drop, though slightly less.

VARIATION OF VOLTAGE WITH USE

Curves *B* and *C* may be misleading unless certain explanations are made. It will be noticed that after thirty days the voltage goes up at a faster rate than at the beginning of this period. This is due to some extent to the accumulation of impurities during the thirty-day period, but in the main this is due to the great increase in impurities in the diaphragm due to excessive amperage. During this time the amperage was uniformly higher than 1,200 amp., going at times to nearly 2,000 amp. Consequently more brine had to be fed to the cells in a given time, with the consequent increase of impurities in the diaphragm. While the voltage has been corrected for excessive amperage, it has not been corrected for these accumulated impurities. Compare curve *C*, which represents a cell running under the same conditions as that in curve *B* with the exception that the brine is not purified. It will be noticed that the curve rises very rapidly at the start but flattens out as the age increases. This is due to the fact that with more impurities in the brine the plugging of the dia-

phragm was greater and the liquor in the cell rising to its limit automatically checked the inflow of liquor coming in through the float valve. Now cells represented by curve *C* started in at an initial flow of 21.00 c.c. per amp.-hr. (1,200 amp., 26.5 sq.ft. of diaphragm), and at the end of ten days the flow in spite of the increasing static head had been reduced to 7 c.c. per amp.-hr., or only one-third as much as at first. A flow of about 9 c.c. per amp.-hr. is good practice. The cell represented by *C* has had its diaphragm plugged so rapidly that the diaphragm should have been washed at the end of ten days and this washing would not have been entirely satisfactory.

Now cells represented by curves *A* and *B* start in with an initial rate of flow of 30 c.c. per amp.-hr. and at the end of ten days, without any raise of static head, drop to a rate of 15 c.c. per amp.-hr. From the above you would naturally expect a flat voltage curve on curve *B*, as there are few impurities and the flow is so rapid that one would expect that they would lodge only to a small extent in the diaphragm. You would also expect a rapidly rising voltage curve on curve *C*, as we have here all the impurities and the flow is so reduced that they must lodge in the diaphragm.

DIAPHRAGMS IMPROVE WITH USE AFTER WASHING

I wish to bring out another fact oftentimes not appreciated, and that is that washing the diaphragm not only saves the cost of a new diaphragm together with the labor needed to change the same but the washed

diaphragm is actually a better diaphragm than a new diaphragm. In order to show this I submit Fig. 8, corresponding with curve *B* of Fig. 7, showing the effect the washing has on the current efficiency. The ordinates are current efficiencies and decomposition efficiencies and the abscissæ are c.c. of flow per amp.-hr. The heavy black line shows efficiencies in terms of the rate of flow in c.c. per amp.-hr. on a diaphragm which has not been washed out. The dotted line shows the change in current efficiency on same diaphragm after washing with water. It will be noticed that the current efficiency and decomposition efficiency are raised for the same rate of flow in both cases.

If you refer to Fig. 8A, representing curve *B*, Fig. 7, you will see the effect of the second washing. The heavy black line represents the same facts as in Fig. 8. Similarly Fig. 8B and Fig. 8C, corresponding to curve *C*, show that both the current efficiency and decomposition efficiency are raised for the same rate of flow for both efficiencies by washing with water. I have

FIGS. 8, 8A, 8B AND 8C. CURRENT AND DECOMPOSITION EFFICIENCIES, DASHED LINES AFTER FIRST WATER WASH AND SOLID LINES BEFORE WATER WASH

many such charts of cells run under many different conditions and find that practically all show this characteristic. In order that the information contained in the above may be available to users of cells having varying diaphragm areas I will state that these areas of diaphragm in the above cases were 26.5 sq.ft. each. I should like to give more time to this subject, but must drop it at this point in order to take up other subjects.

TABLE VII

Electrolytic Plant of Dill & Collins, July 19, 1919. Current amperes, 1,200

a Cells had been shut down to wash and had just started up, so efficiencies had not been taken.

Average run in days, 165. Average voltage, 3.55. Average current eff., 95.6. Average liters per hr., 16.3. Current held at 1,212 amp. Decomposition efficiency held as close to 50 per cent as possible.

I cannot, however, let the matter drop without giving at least one illustration as to how curve A may be carried out in practice. I submit Table VII, taken from Dill & Collins' plant, July 19, 1919.

AVERAGE DATA NECESSARY

It will be noticed that no cell had been changed for forty-nine days, while the oldest cell was 248 days. It will be noticed that certain cells show an efficiency of over 100 per cent. These are errors which may occur in various ways. The low efficiencies may also be errors. The average efficiency is undoubtedly correct. I shall discuss later some of the factors contributing to calculations of current efficiency in an electrolytic cell, but right here I wish to mention a factor which will show why even though the high and low figures may be wrong, the average of the total may be correct. In testing for the current efficiency of a cell the amount of caustic liquor which runs off in a given period of time is tested for caustic soda and the current efficiency is calculated from the above and the number of amperes passing through at the time. Now if due to evaporation there is an accumulation of salt in the outlet pipe, we would have a slight damming up of caustic in the cathode chamber and we would be getting a less amount of caustic liquor than actually flowed through the diaphragm and consequently the current efficiency for such cells would show lower than the actual. If, on the other hand, the salt which had partially obstructed the flow of caustic liquor

should dissolve out while the test is being taken, the flow from the cell would be greater than the flow through the diaphragm and consequently the current efficiencies for such cells would show higher than they actually are. The caustic solution is always unsaturated as regards both caustic and salt so that the obstructions are bound to dissolve out. Of course the longer the test the less will be the effect of such disturbances. Of course if long tests are taken the efficiencies of all the cells cannot be taken at one time. So the short cell test has a certain advantage, even though there may in a few cases be a small inaccuracy. On a large number of cells it has been found that the increasing flow in some cells compensates for the decreasing flow in other cells, so that the average efficiency for all the cells checks with the efficiency of the plant. Consequently, with this explanation it is better to submit all the figures as taken than to take the risk of rejecting the high and low figures.

The decomposition efficiencies are not tabulated, but each cell is run as close to 50 per cent decomposition efficiency as factory operation will allow. This table is not a selected table, but one which was taken on the date when two of my representatives happened to visit the plant. This is especially instructive in showing how systematic washing of cells combined with efficient management can keep cells from deteriorating. Dill & Collins' plant will show results comparable to the above any day in the year. I have been informed that the carbons in this plant last sixteen to eighteen months.

Compare the life of the carbons in a plant run as above with the life of carbons in a cell using impure brine as in curve C in Fig. 7. In this case the carbons other than the spacing blocks were used up in less than 120 days. In cells represented by curve B the carbons were whole and good for a much longer time.

From the above it will be seen that proper care of an electrolytic cell is as important a factor as the proper care of an engine. Perhaps I can bring this more forcibly to your attention if I give some comparative figures of costs.

TABLE VIII. COST PER TON SALT, DECOMPOSED

	Curve A	Curve B	Curve C
Carbons.....	\$1.03	\$2.11	\$4.34
Asbestos.....	0.38	0.58	0.72
Power.....	9.46	11.85	15.61
Total.....	\$10.87	\$14.54	\$20.67

Assuming carbons at 22c. per lb., asbestos paper at \$1 per lb., 1 hp.-yr. (24 hr. a day) \$40, we find that the costs for these three items alone come to the figures shown in Table VIII.

(Part III will appear in a subsequent issue.)

Lizard-Skin Industry in India

The lizard-skin industry forms a new branch in the hides and skins trade in India, states Consul Foss, of Calcutta. There are being manufactured from these skins, in various shades, ladies' and children's shoes, purses and handbags and other articles which are now being made from calfskin and kid, and the wear has proved to be as good as articles made from glacé kid. The skins, averaging 2 sq.ft., are collected from the jungles of Orissa and manufactured in the tanneries at Cuttack. Prices for the prepared skins are 32c. each and the shoes manufactured from them are being made to order at \$4 per pair.

BY WELLINGTON GUSTIN

Option in a Chemical Contract Must Be Exercised Within a Reasonable Time

Finding that the Chatham Manufacturing Co., seller, did not exercise within a reasonable time an option to increase the total amount of acid sold to the Avery Chemical Co., the Supreme Judicial Court of Massachusetts at Suffolk has ruled denying the seller the right to increase the order from 500 to 2,500 bbl. and claim damages for failure of the chemical company to accept the larger quantity.

Under a written contract the chemical company agreed to buy 500 bbl. of pyroigenous acid at 5c. per gal., the amount to be increased at the seller's option to 2,500 bbl., "shipments to begin as soon as possible." This acid was a byproduct from the distillation of soft pine lumber and formerly was a waste product. At the time of making the contract, in January, 1918, it was in demand for the making of iron liquor used in the dyeing and coloring of khaki cloth for the Government. The demand for this ceased later in 1918, and from that time the acid had no market value. The seller's weekly output was about 75 gal., at a cost of $\frac{1}{2}$ c. a gal.

None of the acid was shipped to the buyer until August, during which month 125 bbl. was received and paid for. After several letters were passed between the parties, the buyer notified seller to ship no more of the acid, conceded its liability for failure to accept 375 bbl. and damages at 4 $\frac{1}{2}$ c. a gal., amounting to \$863.34. The seller attempted to recover damages for the failure to take 2,000 bbl., which, under the option, it claimed the right to deliver. The principal question presented to the court was whether the option, if it should be decided it was exercised by the seller, was exercised within a reasonable time.

No time limit was set for carrying the option into effect. The trial court said that in order to bind the buyer it was essential that the option should have been exercised within a reasonable time, and so the Supreme Court ruled.

WHAT IS A REASONABLE TIME?

Now where all the facts are shown it is a question of law what was a reasonable time for exercise of the seller's option to increase the quantity deliverable from 500 to 2,500 bbl. of acid. The facts show that the contract was made in January, 1919, and various communications were exchanged concerning delays on the part of the buyer, until the seller wrote the buyer Nov. 23, 1918, saying that it expected the buyer to take 2,500 bbl. of pyro acid.

The court thought the delay in exercising this option was not a reasonable length of time, considering the other circumstances that the contract involved called for a kind of acid useful solely for the dyeing of soldiers' clothing. When that demand ceased the acid contracted for was no longer salable, facts which the seller well knew. The court found that with a production of 75 bbl. weekly the 500 bbl. contracted for would be ready for delivery by April 1. No notice was then given that the seller intended to exercise the option, and there

was no such notice until several months later. The court said the option could not remain open indefinitely and the seller knew the war crisis caused execution of the contract. A letter in August was held to extend the time of deliveries and likewise the time for exercising the option. The court here held such extension must be for a reasonable time.

Finding that the notice by the seller that it exercised the option to increase the quantity of acid to be delivered was given after signing of the armistice and cessation of hostilities, when seller knew there was no further demand for its product, the court was convinced that the option was not exercised within a reasonable time. Therefore the seller could not recover on its claim.

Injury to Employee From Fumes in Factory

The Court of Appeals of Georgia has refused to dismiss the amended petition of Ryan, administrator of the estate of Arthur Durant, in his action for personal injuries against the American Agricultural Chemical Co., brought in the Superior Court for Chatham County, Ga.

The amended petition alleged that the chemical company operated a plant for the manufacture of fertilizer and maintained a nitrate tank 8 ft. square, 4 ft. deep and standing 3 ft. above the floor, and that there was another receptacle a few feet from the tank, known as a boot, 18 in. in diameter, 2 ft. deep, the top being flush with the floor, while a lead pipe ran from the bottom of the tank to the boot; that in flushing out the tank an employee was required to hold the nozzle of a hose over the top of a tank, which washed the accumulations in the tank through the pipe into the boot; that vapors and gases arose from the accumulations, which were of a poisonous nature, so that the employee engaged in washing out the tank was required to keep his head to the side of the tank, so as to not inhale the fumes; that Durant, while holding the hose to flush out the tank on orders from his foreman, was subjected to fumes not easily discernible by the sense of smell and his clothing was saturated therewith; that the foreman refused to allow a co-employee to place a sack over the boot to prevent such fumes escaping; that Durant was rendered partly unconscious by the fumes, and while in such condition he wandered to a lower floor of the building and sat down near a mill acid tank, from which dangerous position he was rescued and taken to a hospital in a police ambulance. The petition then alleges that his throat and lungs were seriously affected, to his damage in the sum of \$20,000.

The action was originally brought by Arthur Durant, the employee, but upon his death an administrator was appointed. The questions presented to the court were those of diligence and negligence on the part of the employer in preventing the injury and rescuing the employee, coupled with contributory negligence of the employee. These questions, the court said, were matters of fact peculiarly for the jury to determine, and a court will decline to solve them except in plain and indisputable cases.

Citing a controlling decision in another case, it was said that the allegations do not show, as a matter of law, that no other legal conclusions could be reached than that the employee's injuries were the result of his failure to exercise ordinary care, or that by the exercise of such care the consequences of the employer's alleged negligence could have been avoided.

Engineers and Public Service

An Address Before American Engineering Council of the Federated American Engineering Societies
Outlining Some of the Public Service Problems to Which the New
Organization May Profitably Devote Its Attention

By HERBERT HOOVER*

THIS federation of engineering societies, embracing the membership of between 50,000 and 100,000 professional engineers, has been created for the sole purpose of public service. This initial meeting surely warrants some discussion of a few of the problems to which this organization, for expression of the engineering mind, can quite well give consideration.

Some of the greatest of the problems before the country and, in fact, before the world are those growing out of our industrial development. The enormous industrial expansion of the last fifty years has lifted the standard of living and comfort beyond any dream of our forefathers. Our economic system under which it has been accomplished has given stimulation to invention, to enterprise, to individual improvement of the highest order, yet it presents a series of human and social difficulties to the solution of which we are groping. The congestion of population is producing subnormal conditions of life. The vast repetitive operations are dulling the human mind. The intermittency of employment due to the bad co-ordination of industry, the great waves of unemployment in the ebb and flow of economic tides, produce infinite wastes and great suffering. Our business enterprises have become so large and complex that the old personal relationship between employer and worker has to a great extent disappeared. The aggregation of great wealth, with its power of economic domination, presents social economic ills which we are constantly struggling to remedy.

NO MAN CAN DRAFT A UNIVERSAL PANACEA

I propose to traverse only a small fraction of these matters. I do not conceive that any man, or body of men, is capable of drafting in advance a plan that will solve these multiple difficulties and preserve the system which makes individual initiative possible. We have presented to us economic social patent medicines of one kind or another and, in fact, the great panacea of socialism is today in actual trial in its various forms. In Russia the attempt has been made to apply the most extreme form of complete communism. The Russian experiment is bankrupt in production. The populations of our modern states have been built up to numbers dependent upon an intensity of production that can be maintained only by stimulation of individual effort through the impulse of self-interest, and a departure from this primary incentive to production has now been demonstrated to lead only to famine and flame and anarchy. We have even had a gigantic experiment imposed upon the United States by the war in the necessity to operate a vast merchant marine at the hands of the Government, with a result that should offer little consolation to those who advocate even the mildest application of socialism.

*President, American Engineering Council.

We have built up our civilization, political, social and economic, on the foundation of individualism. We have found in the course of development of large industry upon this system that individual initiative can be destroyed by allowing the concentration of industry and service, and thus an economic domination of groups over the whole. We have therefore built up public agencies intended to preserve an equality of opportunity through control of possible economic domination. Our mass of regulation of public utilities and of many other types of industry, aiming chiefly to prevent combinations in restraint of free enterprise, is a monument to our attempts to limit this economic domination to give a square deal. This regulation is itself also proof of the abandonment of the unrestricted capitalism of Adam Smith. While our present system of individualism under controlled capitalism may not be perfect, the alternative offers nothing that warrants its abandonment. Our thought, therefore, needs to be directed to the improvement of this structure and not to its destruction.

GROWTH OF VOLUNTARY LOCAL AND NATIONAL ASSOCIATIONS

A profound development of our economic system apart from control of capital and service during the last score of years has been the great growth and consolidation of voluntary local and national associations. These associations represent great economic groups of common purpose, and are quite apart from the great voluntary groups created solely for public service. We have the growth of great employers' associations, great farmers' associations, great merchants' associations, great bankers' associations, great labor associations—all economic groups striving by political agitation, propaganda and other measures to advance group interest. At times they come in sharp conflict with one another, and often enough charge one another with crimes against public interest. And to me one question of the successful development of our economic system rests upon whether we can turn the aspects of these great national associations toward co-ordination with one another in the solution of national economic problems, or whether they shall grow into groups for more violent conflict. The latter can spell breakdown to our entire national life.

SERVICE SHOULD BE MOTTO OF ENGINEERS

This engineers' association stands somewhat apart among these economic groups in that it has no special economic interest for its members. Its only interest is the creation of a great national association in public service, to give voice to the thought of the engineers in these questions. And if the engineers, with their training in quantitative thought, with their intimate

experience in industrial life, can be of service in bringing about co-operation among these great economic groups of special interests they will have performed an extraordinary service. The engineers should be able to take an objective and detached point of view. They do not belong to the associations of either employers or labor, of farmers or merchants or bankers. Their calling in life is to offer expert service in constructive solution of problems to the individuals in any of these groups. There is a wider vision of this expert service in giving the group service of engineers to group problems.

We have just passed through a period of unparalleled speculation, extravagance and waste. We shall now not only reap its inevitable harvest of unemployment and readjustment but we shall feel the real effect of four years of world destruction, and from it economic and social problems will stand out in vivid disputation. One of the greatest conflicts rumbling up in the distance is that between the employer on one side and organized labor on the other. We hear a great deal from extremists on one side about the domination of the employer, and on the other about the domination of organized labor. Probably the tendency to domination exists among the extremists on both sides. One of the most perplexing difficulties in all discussion and action in these problems is to eliminate this same extremist. There are certain areas of conflict of interest, but there is between these groups a far greater area of common interest, and if we can find measures by which, through co-operation, the field of common interest could be organized, then the area of conflict could be in the largest degree eliminated.

LABOR ORGANIZATIONS BULWARK AGAINST SOCIALISM

In this connection the employer sometimes overlooks a fundamental fact in connection with organized labor in the United States. This is that the vast majority of its membership and of its direction are individualists in their attitude of mind and in their social outlook; that the expansion of socialist doctrines finds its most fertile area in the ignorance of many workers, and yet the labor organizations, as they stand today, are the greatest bulwark against socialism. On the other hand, some labor leaders overlook the fact that if we are to maintain our high standards of living, our productivity, it can only be in a society in which we maintain the utmost possible initiative on the part of the employer; and further, that in the long run we can expand the standard of living only by the steady increase of production and the creation of more goods for division over the same numbers.

The American Federation of Labor has publicly stated that it desires the support of the engineering skill of the United States in the development of methods for increasing production, and I believe it is the duty of our body to undertake a constructive consideration of these problems and to give assistance not only to the Federation of Labor but also to the other great economic organizations interested in this problem, such as the Employers' Association and the Chambers of Commerce.

THREE CHIEF WASTES OF PRODUCTION

It is primary to mention the three chief wastes in production: First, from intermittent employment; second, from unemployment that arises in shifting of industrial currents, and third, from strikes and lockouts. Beyond this elimination of waste there is another field

of progress in the adoption of measures for positive increase in production.

In the elimination of the great waste and misery of intermittent employment and unemployment we need at once co-ordination in economic groups. For example, our engineers have pointed out time and again to the bituminous coal industry where the bad economic functioning of that industry results in an average of but 180 days' employment per annum, where a great measure of solution could be had if a basis of co-operation could be found among the coal operators, the coal miners, the railways and the great consumers. The combined result would be a higher standard of living to the employees, a reduced risk to the operator, a fundamental expansion of economic life by cheaper fuel. With our necessary legislation against combination and the lack of any organizing force to bring about this co-operation the industry is helpless unless we can develop some method of governmental interest, not in governmental ownership but in stimulation of co-operation in better organization.

In help against the misery in the great field of seasonal and other unemployment we indeed need an expansion and better organization of our local and federal labor exchanges. We have a vast amount of industry, seasonal in character, which must shift its labor complement to other industries. The individual worker is helpless to find the contacts necessary to make this shift unless the machinery for this purpose is provided for him.

COLLECTIVE BARGAINING

In the questions of industrial conflict resulting in lockouts and strikes one mitigating measure has been agreed upon in principle by all sections of the community. This is collective bargaining, by which, whenever possible, the parties should settle their difficulties before they start a fight.

It is founded not only on the sense of prevention but on the human right to consolidate the worker in a proper balanced position to uphold his rights against the consolidation of capital. This measure, advocated for years by organized labor, was agreed to by the employers' group in the First Industrial Conference. It has been supported in the platforms of both political parties. The point where the universal application of collective bargaining has broken down is in the method of its execution. The conflict arises almost wholly over the question of representation and questions of enforcement. The employer in some industries denies the right of men other than his own employees to conduct the negotiations. Labor organizations insist that as such negotiations require skill, experience and bargaining freedom they are of more than local application and that thus only can they protect the body of workers by presenting the case on their behalf by skilled negotiators.

The Second Industrial Conference, of which I was a member, proposed a solution to this point by the provision that where there was a conflict over representation the determination should be left to a third and independent party. It also proposed that each party should have the right to summon skill and experience to its assistance. It further proposed that where one of the parties at dispute refuses to enter upon collective bargaining the entire question should be referred to an independent tribunal for investigation as to the right and wrong of the whole dispute—but only for investi-

gation and report. That conference, embracing both a great employer and a most distinguished representative of organized labor, was completely convinced that the illumination of the public mind as to the rights and wrongs of these contentions would in itself make for material progress in their solution, and that in public education and the condemnation by public opinion of wrong-doing lay the root of real progress. No group should be afraid of authoritative publicity in these matters, and I believe it would greatly advance an understanding of the cause of labor. The conference did not believe that industrial contention could be cured by compulsory arbitration or any other form of governmental repression which must in the end use the jails for enforcement. The principles formulated by that conference should have your consideration.

QUESTIONS DESERVE CAREFUL STUDY BY ENGINEERS

There are questions in connection with this entire problem of employer and employee relationship, both in its aspects of increased production and in its aspects of wasteful unemployment, that deserve most careful study by our engineers. There lies at the heart of all these questions the great human conception that this is a community working for the benefit of its human members, not for the benefit of its machines or to aggrandize individuals; that if we would build up character and abilities and standard of living in our people we must have regard to their leisure for citizenship, for recreation and for family life. These considerations, together with protection against strain, must be the fundamentals of determination of hours of labor. These factors being first protected, the maximum production of the country should become the dominating purpose. The precise hours of labor should and will vary with the varying conditions of trades and establishments, but the proper determination of hours, based upon these factors, is an immediate field demanding attention of engineers. There is no greater economic fallacy than the doctrine that the decrease of hours below these primary considerations makes for employment of greater numbers, and it is an equal certainty that the 84-hr. week of some employments transgresses these fundamentals to a point of inhumanity.

GRADED ADDED COMPENSATION FOR SKILL

There is a broad question bearing upon stimulation of self-interest and thus increase in production that revolves around the method of wage payment. I need not review to you the advantages, difficulties and weaknesses of bonus, piece work, profit- or saving-sharing plans that are in use as a remedy for the deadening results of the same wage payment to good and bad skill alike. The suggestion I wish to put for your consideration is the possible use of another device in encouragement of individual interest and effort by creating two or three levels of wage in agreements for each trade, the position of each man in such scale to be based upon comparative skill and character. This plan should be developed upon the principle of graded extra compensation for added skill and performance above an agreed basic wage. In order to give confidence the classification under such scales must be passed upon by representatives of the workers in such shop or department. This plan is now being successfully experimented with.

We must take account of the tendencies of our present

repetitive industries to eliminate the creative instinct in its workers, to narrow their field of craftsmanship, to discard entirely the contribution to industry that could be had from their minds as well as from their hands. Indeed, if we are to secure the development of our people we cannot permit the dulling of these sensibilities. Indeed, we cannot accomplish increased production without their stimulation. Here again we cannot make an advance unless we can secure co-operation between the employer and the employee. In large industry this mutuality of interest that existed in small units cannot be restored without definite organization.

SHOP COMMITTEES

There has been a great increase in shop committees as a method of such organization. Where they have been elected by free and secret ballot among the workers, where they are dominated by a genuine desire on both sides for mutual co-operation in the shop, they have resulted in great good. One of the most important phases of that good has been the tendency to turn the aspect of some foremen from that of slave-driving to leadership. And a great good has been possible by the encouragement of men to creative effort, in the stimulation of their minds as well as their hands to the solution of these problems. It makes for pride of craftsmanship and is a real effort to offer them an opportunity of self-expression. Organized labor has opposed some forms of these committees because of the fear that they may break down trade organization covering the area of many different shops. There is economic reason for this fear in certain cases, deeper than appears upon the surface.

One of the greatest accomplishments of organized labor has been the protection of the workers from the unfair employer, and it is worth the employer's notice that this is at the same time the protection of the fair employer from the unfair competition of the sweat-shop. Again, I believe the engineers could assist in the erection of a bridge of co-operation if organized labor, which has already made a beginning, would extend more widely its adoption of the principles of a shop committee settling its problems of wage and conditions of labor in general agreement and applying its energies through shop committee organization to development of production as well as to the correction of incidental grievances. There would be little outcry against the closed shop if it were closed in order to secure unity of purpose in constructive increase of production by offering to the employer the full value of the worker's mind and effort as well as his hands.

INCREASED PRODUCTION

There is an immediate problem in increased production that is too often overlooked by the theorist. While it is easy to state that increased production will decrease cost and by providing a greater demand for goods secure increased consumption and ultimate greater employment, yet the early stages of this process do result in unemployment and great misery. It takes a variable period of time to create the increased area of consumption of cheapened commodities, and in the meantime, when this is translated to the individual worker he sees his particular mate thrown out of employment. We accomplish these results over long periods of time, but if we would secure co-operation to accomplish them rapidly we must take account of this unemployment and we must say to them that if the community is to benefit

by the cheapening costs, and thus the increased standard of living, or alternatively if the employer is to take the benefits, the entire burden should not be thrust upon the individual who now alone suffers from industrial changes. Nor can this be accomplished except by co-operation between groups. In fact, the whole problem of unemployment needs earnest consideration.

SUMMARY

In summary, the main point that I wish to make is this: that there is a great area of common interest between the employer and the employee through the reduction of the great waste of voluntary and involuntary unemployment and in the increase of production. If we are to secure increased production and an increased standard of living we must keep awake interest in creation, in craftsmanship and the contribution of the workers' intelligence to management. Battle and destruction are a poor solution of these problems. The growing strength of national organizations on both sides should not and must not be contemplated as an alignment for battle. Battle quickly loses its rules of sportsmanship and adopts the rules of barbarism. These organizations—if our society is to go forward instead of backward—should be considered as the fortunate development of influential groups through which skill and mutual consideration can be assembled for co-operation to the solution of these questions. If we could secure this co-operation throughout all our economic groups we should have provided a new economic system, based neither on the capitalism of Adam Smith nor upon the socialism of Karl Marx. We should have provided a third alternative that preserves individual initiative, that stimulates it through protection from domination. We should have given a priceless gift to the Twentieth Century.

I am not one of those who anticipates the solution of these things in a day. Durable human progress has not been founded on long strides. But in your position as a party of the third part to many of these conflicting economic groups, with your lifelong training in quantitative thought, with your sole mental aspect of construction, you, the engineers, should be able to make contribution of those safe steps that make for real progress.

Paper From Veneer Waste*

Raw material suitable for the manufacture of high grades of paper is found in wood wastes from veneer factories. The cores of many kinds of veneer logs, now used in large part for fuel, would make excellent pulpwood. In addition, a large part of the clippings and small veneer waste probably could be turned into pulp stock with profit.

Among the veneer woods whose waste has paper-making possibilities are red gum, yellow poplar, cottonwood, birch, tupelo, basswood and beech. Many veneer factories cutting these species are already within shipping distance of pulp mills: In certain other cases veneer factories are so grouped that they might furnish pulpwood enough to warrant the erection of a centrally-located mill. Other economic factors being favorable, such a mill could profitably operate on a daily supply of veneer waste equivalent to fifty cords of ordinary pulpwood. Of course, the construction of a mill should be undertaken only upon the advice of a competent mill engineer after a careful survey of local conditions.

*From *Technical Notes*, Forest Products Laboratory.

Cast-Iron Thermit Welds

Almost every day in various industries the question arises as to the feasibility of welding cast-iron sections of widely divergent sizes and shapes. The following explanation may therefore be of interest to those contemplating repairs of this nature:

In thermit welding the superheated steel produced by the reaction, when tapped into the mold surrounding the weld, fuses back into the fractured parts 2 or 3 in. on either side and the whole mass solidifying at one time effects the repair. The excess metal of the weld may then be removed or not, as the necessity indicates.

In cast-iron welding steel is the welding medium and the weld material will therefore necessarily consist of a mixture of this steel and the cast iron of the parts being welded. The graphitic carbon in the cast iron combines with the thermit steel, thus making a high-carbon steel which usually can be machined only by grinding. This material, however, is not so brittle as cast iron and is physically stronger.

In the second place, in considering thermit repairs of cast iron it should be borne in mind that the weld material is steel and therefore has double the shrinkage of the cast iron. This difference in shrinkage is of no importance where the section being welded is approximately square or equi-axed. Where, however, the length of the section at the fracture is four or five times its thickness this difference in shrinkage is evidenced by one or more minute cracks perpendicular to the line of the weld and extending through the weld material only. These cracks are naturally caused by the difference in shrinkage, the cast-iron parts tending to restrict the shrinkage of the steel along the length of the piece. Such hairline cracks will be found in the welding of sections such as, for instance, 12 x 24 in., but would not be found in sections 12 x 12 in. The cracks are often unimportant, as they are parallel to the line of strain.

The experience of the Metal & Thermit Corporation over a long term of years with literally thousands of cast-iron welds proves conclusively that where the length of a fracture is not more than four or five times its thickness and where the subsequent machining can be accomplished by grinding, a thermit weld can be made and will invariably be successful.

Foreign Trade of France for the First Nine Months of 1920

The total French foreign trade for the first nine months of 1920 amounted to 43,746,782,000 fr. (franc — \$0.193 at the normal rate) against 31,271,637,000 fr. for the corresponding period of 1919, reports Consul General Thackara of Paris. The imports of food products for the January-September period of 1920 were valued at 6,727,751,000 fr., against 7,413,563,000 fr. for the first nine months of 1919; industrial materials, 12,618,645,000 fr. against 9,542,226,000 fr.; manufactures, 7,842,675,000 fr., against 7,611,631,000 fr. The exports of food products amounted to 1,529,501,000 fr. against 709,085,000 fr.; industrial materials, 3,661,821,000 fr., against 1,205,090,000 fr.; manufactures, 10,589,520,000 fr., against 4,174,361,000 fr.; and postal packages, 776,868,000 fr., against 615,681,000 fr. The adverse trade balance for the first nine months of 1920 was 10,631,360,000 fr., against 17,863,203,000 fr. for the corresponding period of 1919.

Some Deep-Etching Experiments on New Steel Rails

BY GEORGE F. COMSTOCK

IN VIEW of the interest that has been aroused recently in the subject of deep-etching of rails and the markings shown thereby, a few experiments were made with this method of etching on some of the large collection of new steel rails that have accumulated in this laboratory from previous work. Some facts were brought out by these experiments which, while possibly not of entirely general application, may nevertheless be worth publishing as affording an additional scrap of evidence on a point which has not received much attention in the numerous discussions of this etching method.

Most of the papers on this subject give the impression that the authors have considered all depressions, eaten out of a rail-section that was etched for several hours in strong hot acid, to be the result of pre-existing cracks or a shattered condition of the steel. Technologic Paper 156 of the Bureau of Standards, entitled "Metallographic Features Revealed by the Deep Etching of Steel," by H. S. Rawdon and S. Epstein, is an exception to the above statement, and a study of

this comprehensive discussion of the subject shows that these authors appreciate the action of this etching on segregated streaks as well as its action on fissures or cracks. The statement has occurred several times in papers on this subject that the fissures or shattered condition have been found in new rails as well as in rails that had been in track, but no evidence has ever been seen by the writer as to the frequency with which this condition is met in new rails. It was decided, therefore, to examine some of the new rails in our large collection of samples, to see what we could find in them by deep etching.

The samples chosen were all hot-sawed sections of A-rails, half of them being rails made according to usual practice and more or less segregated, and half being titanium-treated rails having a uniform structure. Lengthwise sections 4 or 5 in. long were cut parallel to the base of the rail, and a little below the center of the head, and these were all boiled for several hours in strong hydrochloric acid, until their macrostructures were prominently developed. The etched sections were washed, dried carefully, and rubbed with a little oil to retard rusting, and were then photographed, with results as shown in the accompanying illustrations.

The homogeneous rails show sections free from any pits or markings except the lines due to the rolling out

Horizontal longitudinal sections cut a little below centers of heads: section from separate heat, and upper and lower rows from different small transverse cracks in small s

1 deeply etched. Each pitted segregated streaks in all, and two

Horizontal longitudinal sections cut a little below centers of heads of new titanium-treated open-hearth A-rails, and deeply etched. Each section from separate heat, and upper and lower rows from different mills. Etching shows rolled-out dendrites only.

of the original dendritic structure of the ingots. The ordinary segregated rails, however, show numerous deep streaks or elongated pits that are due not to any unsound or shattered condition of the steel, but merely to segregation of impurities, chiefly sulphur, which caused the metal in those streaks to dissolve faster. It is important that such segregated streaks should not be confused with cracks in the steel, yet the method of examination by deep etching gives the same indication for both kinds of defect.

The section illustrated in the upper right-hand corner of the photograph of the segregated rails shows two small transverse pits, one associated with a double segregated streak, and one apparently separated from any such streak. These could hardly be anything but enlarged cracks in the steel, so that we have here evidence of this condition occurring in a new rail that has not been in service. The twelve samples examined by deep etching do not probably constitute a sufficiently extensive test for a good determination of the frequency of occurrence of this defect in new rails, but we know at least that it was found in only one out of twelve subjected to deep etching, and indeed this is the only new rail in which such cracks were found out of about sixty new A-rails which have been exhaustively tested in this laboratory by various physical and metallographic methods. Thus it seems probable, from our work at least, that the shattered condition found so commonly in rails that developed transverse fissures in track is a very rare occurrence in new rails. Evidence

on this point from those who have investigated it more extensively would be of considerable interest.

It might well be noted in this connection that since only one rail in a thousand develops transverse fissures, every transverse fissure might well be the result of shattered metal in a new rail, without any such defect being found in an investigation of only sixty representative rails. In other words, shattered metal in new rails may be quite a rare occurrence and still account for every case of transverse fissures.

Europe's Sugar Production

In sugar production Germany has suffered perhaps more than any other country as a result of the war. Germany was the great sugar-producing area, but now she is unable to supply her own needs. Meanwhile Cuba has increased its output to still greater proportions, providing now about 90,000,000 hundredweight annually. The figures for sugar production in the principal European countries, as given in *The Review* of Oct. 15, 1920, are as follows:

Countries	1913-14 Cwt.	1919-20 Cwt.
Germany.....	54,766,000	15,000,000
Austria-Hungary.....	33,765,000	11,700,000
Netherlands.....	4,628,000	4,760,000
Sweden.....	2,744,000	2,900,000
Denmark.....	2,914,000	3,200,000
Belgium.....	4,580,000	2,540,000
France.....	15,620,000	3,500,000
Russia.....	33,760,000	7,000,000
Other countries.....	10,856,000	6,000,000

Wilmington and the Chemical Industry

Aside From the Well-Known Powder and Explosives Plants the Industrial Activities of Wilmington, Del., Include Such Chemically-Controlled Industries as: Cotton Goods Finishing; Glazed Kid Leather; Lithopone; Vulcanized Fiber; Pulp and Paper

MENTION of Wilmington, Del., invariably brings to mind the explosives industry, which is so highly developed in the district immediately surrounding the city. This instinctive association has become so strong that the extensive industrial enterprises in other lines are often lost sight of. Indeed, even many of the members of the Delaware Section of the American Chemical Society found at the conclusion of the regular meeting held Thursday evening, Nov. 18, that they had not fully appreciated the magnitude of the various chemically-controlled industries in the vicinity of Wilmington. The papers read at this meeting are given in abstract below.

The Finishing of Cotton Goods

Gray goods, as cotton goods are called as they come from the loom, must be finished to make them marketable. The cotton mills sell their product to merchants known as converters, who combine small orders so that the finishers are able to maintain quantity production. The operations involved in finishing cotton goods were outlined by D. S. Ashbrook, superintendent, Joseph Bancroft & Sons Co. This finishing plant is the largest single plant of its kind in this country, having a maximum production of 160,000,000 yd. per year.

After singeing and wetting out, the natural waxes and warp sizing are removed from the gray goods by boiling 9 to 12 hr. under 12 to 15 lb. steam pressure with a 3 to 4 deg. Tw. caustic soda solution in horizontal Mather & Platt kiers having a capacity of about 10,000 lb. of cloth per operation.

The cloth is then stretched on the mercerizing range—two parallel endless chains 75 ft. long made up of iron clips so arranged that the greater the tension the tighter the hold on the selvage of the cloth and impregnated with 30 per cent NaOH solution at 50 to 60 deg. F. After washing, bleaching with sodium hypochlorite, and dyeing by the process best adapted to the type of dye used, the cloth is ready for finishing. The speaker chose a lining sateen as illustrative of the more than two hundred finishes used by this company.

FINISHING PROCESS

In the case of a lining sateen the sizing depends on the weight of cloth desired and on the finish. High-grade cloths are merely oiled to produce a suitable softness. Low-grade cloths are sized with starch and oil. Each of the common starches has peculiar properties of its own and gives a distinctive feel to the cloth. Wheat flour, wheat, corn, cassava, potato, sago and rice starches, corn and potato dextrines are used. The cloth is now stretched, smoothed out on a seven-roll calender and satin finished on a hydraulic schreiner having a steel roll, engraved with fine diagonal lines (250 per in.), which is forced against the face of the cloth by a pressure of 30 to 45 tons at a temperature of 300 to 400 deg. F. The final operation consists in breaking up

any hardness in the finish by steel blades or rollers set with brass-headed tacks.

Manufacture of Glazed Kid Leather

It is not ordinarily realized that with the exception of North America practically the whole world regards the goat as an important source of meat and milk. About 100,000,000 raw goatskins are obtained every year, chiefly from India, China, Europe, Africa, South America and Mexico. Of these about 50,000,000 are sent to the United States, a single company tanning 12,000,000 skins. The manufacture of glazed kid from these skins was described by F. J. Blatz, plant superintendent, Amalgamated Leather Co. Wilmington and Philadelphia produce 80 to 90 per cent of the glazed kid in this country.

BEAM HOUSE PROCESSES

The dry or salted skins are soaked in water, trimmed and treated with lime liquor from 8 to 12 days. The hair and flesh are removed on dehairing and fleshing machines and the excess lime is removed by bating with oropon. On slating machines dull revolving slates are brought into contact with the grain of the bated skins and pull out all dirt and fine hair, clearing the skins for tanning.

TANNING.

In tanning goatskins the two-bath chrome process is used almost exclusively. The skins are placed in a solution of sodium bichromate acidified with hydrochloric acid. The next day the skins are bright yellow in color, but are not tanned, since the yellow color can be removed by washing in water. By immersing in a solution of sodium hyposulphite acidified with HCl the chromic compounds are reduced and combine with the skin to form leather. Only two days are required for this process. A portion of the free sulphur liberated from the sodium hyposulphite is apparently also taken up by the skin, since the results are superior to those obtained by using sodium bisulphite. About 1 lb. of sodium bichromate is required for 1 doz. skins. Water is now removed on striking-out machines and the skins are shaved on the flesh side. Unless this were done the backbone, which is thicker than the rest of the skin, would show as a black line on glazing.

COLORING

The skins are weighed and placed in revolving drums with suitable dyes and vegetable extracts, the majority being made into brown and black leather. After coloring the skins are given a bath of fat liquor, compounded of soap, oils and egg yolk. These substances give the leather its soft feel. This is followed by stretching on a putting-out machine, and oiling off with a thin coat of neatsfoot oil and glycerine, which holds the grain fine and silky. Drying brings the skins to the "crust" condition—that is, hard and stiff. They

are piled in cool rooms for a week, dampened with water and put through a staking machine which loosens all the fibers.

FINISHING

The skins are now in a soft, pliable condition. They are given a coating of egg albumen, and gum, blood and nigrosine are usually added to brighten the gloss and blacken the grain. The glaze is produced on the dried skins by the friction of a moving agate cylinder and a stationary leather strap. Three coatings and glazings are usually required.

Measuring, sorting and bundling complete the process.

Lithopone

A paper on the manufacture and uses of lithopone, prepared by A. S. Krebs, treasurer, Krebs Pigment & Chemical Co., was read by Donald Ross, chief chemist.

The manufacture of lithopone is divided into three steps: The production of a pure barium sulphide solution; the preparation of a pure zinc sulphate solution; the manufacture of lithopone from these two solutions.

BARIUM SULPHIDE SOLUTION

The most important raw material is barytes. This is now obtained chiefly from Georgia, although some has gone into the lithopone business from Tennessee and Missouri. The ore deposits of Georgia can be worked satisfactorily with a steam shovel, whereas most Tennessee and practically all Missouri deposits are so small that they are mined by pick and shovel.

Barytes as received at the factory is crushed, mixed with coal and burned at 1,200 to 1,300 deg. C. from 2 to 3 hr. in rotary kilns. The black ash formed is leached, giving a solution of barium sulphide.

ZINC SULPHATE SOLUTION

In the manufacture of zinc sulphate any form of zinc or zinc oxide such as skimmings, zinc ash from galvanizing kettles, impure oxides or zinc carbonate ores may be dissolved in sulphuric acid. Zinc sulphide or roasted zinblende may also be used. The resulting solution is purified by various oxidizing processes, depending on the nature of the liquor.

LITHOPONE

By mixing proper proportions of the zinc and barium liquors, lithopone is precipitated. Plate and frame presses or Oliver continuous filters are used in filtering the pigment and the cake is dried and fed into muffle furnaces heated to about 500 deg. C. When uniformly heated the material is raked out, quenched in water and ground to remove grit due to sand from the furnace walls or to the sintering of overheated particles of lithopone. The ground pulp is washed, filtered, dried, pulverized, sometimes air floated, and packed in barrels of 400 lb. or bags of 50 lb.

USES OF LITHOPONE

Lithopone is peculiarly well adapted to the manufacture of paints for interior work, such as flat wall paints with chinawood or soya bean oil vehicles and mill whites. In whiteness it is surpassed only by the finer grades of zinc oxide. It has a low oil figure—that is, there can be incorporated in a gallon of oil more pounds of lithopone than zinc oxide. Partly due to this reason and partly to its capacity, lithopone paints have excellent covering power. Indeed, in this respect it is probably the best pigment.

When lithopone is properly compounded with sublimate lead or zinc oxide and appropriate vehicles, an excellent outside paint results, the use of which is rapidly increasing.

Large quantities of lithopone are also used in the rubber industry, in the manufacture of linoleum, wall paper, window shades and printing inks. The lithopone industry has grown from 920 tons in 1900 to a production of 79,619 tons in 1919, and it is expected that the 100,000-ton mark will be reached in 1920 or 1921.

Vulcanized Fiber

The manufacture, properties and uses of vulcanized fiber were discussed by Jay Robinson, of the American Vulcanized Fibre Co. The annual production of vulcanized fiber in this country is about 20,000,000 lb., about 60 per cent of which is made within a radius of twelve miles of Wilmington.

MANUFACTURE OF VULCANIZED FIBER

Cotton rags are the chief source of the fibrous materials used, although cotton hull, cotton linters and other materials are not uncommon. From these a special porous paper is made without sizing or loading. For best results, the fibers must be long and uniform. Consequently, cotton linters, which are short-fibered and knotty, do not make a satisfactory paper. While new rags are used largely in making writing paper, book-paper, etc., old rags are preferred in the manufacture of fiber paper, as they are softer than new rags. It seems that the older and dirtier the rags are when received at the mill, the better paper they make.

Rolls of the special paper are now made into vulcanized fiber by passing the paper sheet over heated cylinders, through a bath of zinc chloride maintained at about 70 deg. C. and 100 deg. F. It is then rolled up over large heated drums to the desired thickness. The zinc chloride hydrolyzes the cellulose and gelatinizes the surface to such an extent that the paper unites and forms an almost homogeneous mass.

The "green" fiber is then washed in zinc chloride baths of progressively diminishing concentration until it is commercially pure—that is, contains less than 0.15 per cent chlorine. This process is of necessity very slow and any attempts to expedite it are likely to result in an inferior grade of fiber, or in blisters due to increased osmotic pressure. Three to four weeks are required to wash 1-in. fiber, while 2-in. fiber takes six to eight months. The wet, pure fiber is dried to 8 per cent moisture at 100 to 160 deg. F., pressed and calendered. Vulcanized fiber contains from 5 to 8 per cent ash.

PHYSICAL AND MECHANICAL PROPERTIES

The finished product, which has shrunk to about one-half its original thickness, is a homogeneous material with a perfectly smooth, even surface that readily takes a high polish. No ordinary force will crush, break or split it. It can be turned, tapped, threaded, drilled, stamped, cut, sawed, riveted, embossed and bent, but it cannot be molded. The material is resilient, fire-resisting and has a low coefficient of friction. It does not rust, corrode or deteriorate with age like metal, does not scar like leather and does not have the weaknesses of wood.

Vulcanized fiber is not waterproof, but immersion in hot or cold water does no harm, as it resumes the original dimensions and properties on drying. By

special treatment, vulcanized fiber can be made sufficiently moisture-proof for ordinary use. Neutral salts, solvents and oils are without effect, but mineral acids cause disintegration in time.

It is possible to vary the mechanical and physical properties within fairly wide limits by proper manipulation of the chemical treatment or by varying the quality of the original paper. For this reason, care should be exercised in the selection of the proper grade to suit particular requirements. The two chief grades are hard and flexible. Pliability is secured in the latter grade by calcium chloride or glycerine treatment. Hard vulcanized fiber is most extensively used for mechanical purposes and as an insulator in dry places by manufacturers of electrical equipment.

A comparison between some of the properties of vulcanized fiber and other materials is given in Table I.

TABLE I. SOME PROPERTIES OF VULCANIZED FIBER	
SCLEROSCOPE HARDNESS	COMPRESSIVE STRENGTH
Vulcanized fiber..... 25 to 50 Lb. per Sq. in.
Copper..... 15	Vulcanized fiber..... 33,000 to 13,000
Bessemer steel..... 26.6	Tin..... 6,100
Cast iron..... 33.3	Aluminum, cast..... 12,000
Tool steel..... 37.8	Granite..... 19,100
High carbon steel..... 86.1	Marble..... 12,700
	Paving brick..... 10,000
	Porcelain..... 15,000
	Copper, cast..... 39,000 to 18,000
TENSILE STRENGTH	DIELECTRIC STRENGTH
..... Lb. per Sq. in. Volts per Mm.
Vulcanized fiber..... 8,000 to 13,000	Vulcanized fiber..... 6,000 to 16,000
Zinc, cast..... 1,000 to 6,000	Asbestos paper..... 4,000
Tin..... 1,000 to 5,000	Porcelain..... 9,000 to 16,350
Porcelain..... 1,800	
Aluminum, cast..... 11,000 to 16,500	
Aluminum, rolled..... 16,500 to 22,100	

The initial cost of vulcanized fiber is slightly more than that of mica, porcelain, glass, wood, leather, hard rubber and various metals, but on account of its longer life it is more economical in the end. Sheets are supplied from 0.005 to 2 in. thick, in widths and lengths up to 48 x 80 in.; rods and bars $\frac{3}{4}$ to 2 in. thick by 72 in. long; tubes $\frac{1}{4}$ to 6 in. inside diameter by $\frac{1}{4}$ to 6 in. outside diameter by 30 in. long; rolls from 0.005 to 0.025 in. thick.

USES OF VULCANIZED FIBER

As insulation, vulcanized fiber is found everywhere. It makes noiseless, oil- and current-proof gears and pinions. When meshed with metal, such gears will increase the life and efficiency of the whole gear train. Vulcanized fiber valves have given continuous service for over three years in feed water pumps, pumping hot water at 212 deg. F. against 150 lb. pressure. Because of its unusual wearing qualities, vulcanized fiber is being used for mechanical parts such as friction disks and washers, bushings, bearings, brake shoes, gaskets, packings, wheels, etc.

However, in spite of its wide usage, in practically every plant there are countless places where more expensive and less serviceable materials are still being used.

Paper Making in Wilmington

Some notes on paper making in Wilmington were presented by J. H. Plumstead, superintendent, Delaware Mills, Jessup & Moore Paper Co.

The first machine-made paper in the United States was manufactured during the early part of the nineteenth century in a small mill at or near the site of the present Augustine Mill of the Jessup & Moore Paper Co.

¹See "Vulcanized Fiber," by Charles Almy, Jr., MET. & CHEM. ENG., vol. 13, p. 716, Oct. 15, 1915, and "Electrical Properties of Vulcanized Fiber," by William Eves, 3d, Electrical World, vol. 71, p. 190, Jan. 26, 1918.

on a cylinder machine invented by the owner of the mill. While this invention is the greatest single event in the history of paper making to which Wilmington can lay claim, it may be stated in a general way that this entire vicinity has been very closely identified with paper making from the time paper was entirely handmade down to the present day.

The more important grades of paper may be conveniently classified according to use as follows:

GRADES OF PAPER

Newsprint is a mixture of unbleached ground wood and sulphate or sulphite process wood pulp with a small amount of china clay to give opacity and weight and some ultramarine to offset the yellow cast of the unbleached fiber. Newsprint stock receives little mechanical treatment or beating before going to the paper machine.

Book, magazine, litho and the cheaper writings are made from soda, sulphate or sulphite process wood pulp bleached, loaded with china clay to give weight, beaten more than newsprint, tinted or left natural as desired, and sized with glue, casein, rosin, starch, dextrine or parchementizing chemicals to make the sheet impervious to ink. The paper may be calendered by passing it over heated rolls or surface coated and calendered.

Wrapping and tissues are usually made from wood fiber produced by chemically treating a long-fiber wood just enough to break down the cementitious materials. The fibers are not bleached and loading, sizing and coloring matters are not usually added.

High-grade writings, bonds, ledgers and all papers that are sold with the thought that they may be kept for many years are made from cotton fiber itself—that is, from selected rags and cuttings. The mechanical treatment is very similar to that used on book paper.

FUTURE OF WILMINGTON'S PAPER INDUSTRY

Mr. Plumstead outlined the sources of the raw material—cellulose—the operations involved in converting this into paper, and said in conclusion that some of the enormous plants built on sites where water power and timber abound were on the verge of shutting down because, having exhausted the raw material near at hand, they have neither navigable waters nor good railroad facilities to fall back on. Not so with Wilmington. A railroad center with a waterfront which is constantly being improved, raw material supply and markets linked in a way that cannot but make for growth and long industrial life, Wilmington's future in pulp and paper making bids fair to be brilliant.

Pacific Roofing Co. Experimenting on Wallboard

The Pacific Roofing Co. has developed a magnesite quarry on the Pacific Great Eastern Ry., erected an experimental plant for the manufacture of wallboard from sawdust, calcined magnesite and magnesium chloride, and has on exhibition in Vancouver a supply of the finished product, which has attracted considerable attention. The company will erect in the vicinity of Vancouver a magnesite calcining plant capable of treating 5,000 tons of magnesite and of producing 12,500,000 ft. of wallboard annually.

The new industry is somewhat in the nature of an experiment, but if there is a demand for the material the size of the plant will be increased.

A. C. S. Intersectional Meeting of Chicago and Milwaukee Sections

ON INVITATION from the Milwaukee Section the members of the Chicago Section of the American Chemical Society visited Milwaukee the afternoon and evening of Nov. 20. The meeting was called at the Milwaukee Athletic Club.

Dinner was served in the club grill, followed by the evening program. This took the form of an industrial symposium under the direction of W. Lee Lewis, and John Arthur Wilson opened with the following paper:

THEORY VS. PRACTICE AND TRADE SECRETS FROM THE VIEWPOINT OF THE INDUSTRIAL CHEMIST

Since the development of both science and industry is materially assisted by free discussion, it is rather disconcerting to a young enthusiast to find his fellow industrial chemists holding theory in mild contempt and refusing to discuss practice for fear of divulging trade secrets. Although this unwillingness on the part of the industrial chemist to discuss either his science or practice is gradually disappearing, it is still sufficiently widespread to warrant an investigation into the cause.

Often a young chemist leaves school to enter one of the more complicated chemical industries, say that of leather manufacture, where he finds his training in theoretical chemistry of very little immediate value because of its inadequacy to deal with the behavior of the several hide proteins under the conditions of liming, bating, pickling, tanning, fatliquoring and dyeing. If he does attempt to institute a change for the better in one of these operations, the probability is that the stock on which the change is made will be damaged, if not totally ruined. In contrast, he sees an army of unschooled men turning out an unexcelled product. Before he can become of any great value to his firm he must either greatly extend his knowledge of chemistry to cover the tanning operations, or else master the art as conducted in the plant. He really should do both, but he too often feels compelled to give up the pursuit of theoretical chemistry in order to get quicker results by devoting all of his time to plant operations. The advance of science soon leaves him behind and he becomes more and more reluctant to enter theoretical discussions because of the fear, perhaps only subconscious, that a display of ignorance will injure his reputation.

Having become a practical man, however, he can scarcely avoid being drawn into discussions of practice occasionally, and he can often add many facts to such a discussion as, for example, that increasing the salt content of a given liquor produces certain unexpected results. But when an explanation of the phenomenon is sought, involving theoretical chemistry, a most embarrassing situation would follow were it not for the invention of the magic words "trade secret." As soon as he feels himself getting into deep water, he has only to express regret at not feeling free to go more deeply into the discussion, and his reputation is saved. The term "trade secret" is doubly useful, for it not only hides one's ignorance, but actually tends to create a sensation of wonderment.

The remedy is to make it clear to young men leaving school that sound development of a chemical industry requires a knowledge of the basic principles underlying the several processes and that, while it is essential to master the practice of the industry, it is also essential to seek to explain every operation, and this requires

the vigorous pursuit of theoretical chemistry far beyond anything learned at school. While the man who follows this advice may seem to make less headway during the first year than his more practical brother, in the long run he will probably reach a goal entirely out of reach of the man whose theoretical training stops with his graduation.

Industries differing widely in practical procedure are governed by the same physical and chemical laws and the derivation of fundamental principles furnishes a common ground for work and discussion by chemists in every walk of life. With the majority of industrial chemists keeping pace with theoretical chemistry, there would be little need to resort to subterfuges to avoid discussions and the term "trade secret" would become as rare as the thing which it signifies.

DISCUSSION

Otto Eisenschiml described a meeting of foremen and superintendents he had attended some time ago where it was intended to interchange trade secrets of the linseed oil industry. Each one present was asked to write down his best secret and inclose it in a sealed envelope. When the envelopes were later opened fifty of the formulas were found to be identical. At a similar informal meeting of varnish makers the pertinent discovery was made that they were all familiar with the same procedure in manufacture.

Paul Van Cleef and Mr. Nash believed in the need for secrecy, not so much of chemical formulas, but in mechanical methods of preparation.

Dr. Leech, speaking from the viewpoint of the medical profession, said there was nothing of greater handicap to public health than the trade secret. Medical formulas surrounded by deep secrecy and mysticism used in patent medicines, and for which marvelous curative properties are claimed, work untold damage to the well being of the public.

Dr. Redman spoke for the new industries on the firing line of research, where industrial application of new discoveries involve trade secrets of immense money value. Such research findings as cannot be patented must here be kept secret. Speaking of the established industries, we should break the ice, interchange information and do away with the autocratic foreman.

Other speakers, including Messrs. Kadish and Prentiss, were in favor of the general interchange of information between industrial chemists and managers.

Mr. Prentiss made the speech presenting, in behalf of the members, a gold A.C.S. pin to John Arthur Wilson, chairman of Milwaukee Section, for his competent leadership of the work during a most successful year. He touched briefly on the co-operation with the Mayor's office, the city library and the review of the report for the city on the new \$5,000,000 water and sewage project.

While the foregoing paragraphs may cover the serious facts of the meeting in brief, the measure of high spirits and good comradeship cannot be expressed in the space available. Many hearty informal talks of good will and joint interests interspersed with the above made the occasion one of close communion. Close acquaintances, old and new, talked far into the night at the club quarters where the visiting members were entertained. Another intersectional meeting was promised at Chicago in the near future. Among the ladies present were Mrs. L. V. Redman, Mrs. W. Lee Lewis of Chicago and Mrs. S. E. Layman of Milwaukee.

Current Events

in the Chemical and Metallurgical Industries

Chemical Manufacturers to Meet Entomologists

Chemical features of boll weevil control are to be discussed at a series of meetings which will begin in New York, Dec. 6, of manufacturers of arsenates, entomologists and representatives of cotton growers. The conferences are under the auspices of the Crop Protection Institute. The organization of this institute is just being perfected by the National Research Council.

Dusting the cotton plant with arsenates has proved to be the most promising method of boll weevil control. One of the purposes of the conferences is to standardize the arsenates. The intention is to acquaint the manufacturing chemists with the machinery used in applying the arsenates. Attention also is to be given to standardization of the machinery.

This is the type of work to be undertaken by the newly formed Crop Protection Institute. Since chemists play an important part in the eradication and control of insect and fungus pests it is expected that they will have an important part in the work done by the new institute. In fact, G. R. Cushman, of the General Chemical Co., headed the committee which recommended the formation of the Crop Protection Institute. The trustees of the institute are chosen from entomologists, manufacturing chemists, phytopathologists, and a representative of the National Research Council. Mr. Cushman, F. O. Moburg of the Rex Chemical Co. and P. W. Pickard of the Bowker Insecticide Co. are the trustees representing the chemical industry.

Technical Men of Baltimore Organize Engineers' Club

For some time past the technical men of Baltimore and vicinity have felt the need of a central meeting house or club where meetings could be held and where it would be possible to combine the meeting place with the usual facilities of a club. The rapidly increasing number of engineers, chemists and other technical men employed in Baltimore has made it difficult for the various organizations to hold their meetings in quarters sufficiently large to take care of joint meetings of these societies, and much thought has been given to the question of improving the facilities of the city in this way. Therefore the various organizations have decided to back a new enterprise, to be known as the Engineers' Club of Baltimore. The club will be located in the new Merchants and Manufacturers' Building at the corner of Light and Redwood Sts.

The members of each of the technical associations and societies which have chapters or sections in Baltimore will have the privilege of becoming members of the club, and each organization will be able to hold its meetings in the lecture theater in the club building. The clubrooms, other than the lecture theater, will be a library, reading room, billiard room and dining room. In addition special arrangements have been made with one of the adjacent hotels to provide sleeping accommodations for members of the club or their guests.

Annual Meeting of the American Society of Mechanical Engineers

The American Society of Mechanical Engineers will hold its forty-first annual meeting Dec. 7 to 10, 1920, at the Engineering Societies Building, 29 West 39th St., New York City. The tentative program for the technical sessions is:

Tuesday Afternoon, Dec. 7.—Fuel, Forest and Machine Shop Sections.

Wednesday Afternoon, Dec. 8.—Management, Railroad, Design and Research Sections.

Thursday Forenoon and Afternoon, Dec. 9.—Keynote session on Transportation and second meeting of the Research Section.

Friday Forenoon, Dec. 10.—Design, Textile and Power Sections.

Among the many papers to be presented are:

Fuel Supply of the World, by L. P. Breckenridge.

Low-Temperature Distillation of Coal, by O. P. Hood.

Fuel Conservation, by D. M. Myers.

Processes and Equipment Used in Wood Preservation, by E. S. Park and J. M. Weber.

Principles of Industrial Philosophy, by W. N. Polakow.

The Heat-Insulating Properties of Cork and Lith Board, by A. A. Potter, J. P. Calderwood, A. S. Mack and L. S. Hobbs.

Effect of Fittings on Flow of Fluids Through Pipe Lines, by D. E. Foster.

Textile Fabrics for Mechanical Purposes, by J. W. Cox.

Papers on Future Power Development:

The Policy of Future Power Development.

Effect of Load Factors on Cost.

Effect of Size of Plant on Cost.

Financial and Legal Aspects of Future Power Development.

Mining and Metallurgical Society to Be Formed at Utah University

Plans for the formation of a mining and metallurgical society at the University of Utah have been completed, according to Prof. R. S. Lewis. Membership will be restricted to sophomores and upper class men taking mining, metallurgical, chemical and geological courses, as well as professors in those departments, and officials and employees of the United States Bureau of Mines located at the university. The society will petition the American Institute of Mining and Metallurgical Engineers for a student chapter.

Still Looking for Chemical Director for C.W.S.

The search for a chemical director for the Chemical Warfare Service is continuing, but as yet no one has been found who is willing to take the responsibilities of this position for the \$10,000 salary which is offered. Chemists with the qualifications which General Fries deems requisite are being paid higher salaries in private employment. Pending the selection of a director, Captain D. B. Bradner of the chemical staff at Edgewood Arsenal is made acting chemical director.

Association of Official Agricultural Chemists Meets

The Association of Official Agricultural Chemists met in Washington Nov. 15 to 17, at which time numerous committee reports were received regarding methods for valuation of agricultural, fertilizer, drug and food materials. At this meeting it was announced that the publication has been completed of "Methods of Analysis," which is now available for sale by the secretary, box 744, Eleventh St. Station, Washington, D. C. The *Journal* of the association will present the proceedings of the meeting in full in the near future, as this publication is now appearing again regularly.

Officers for the coming year include: President, W. F. Hand, Agricultural College, Mississippi; vice-president, F. P. Veitch, Bureau of Chemistry, Washington, and secretary-treasurer, C. L. Alsberg.

Referees on subjects of industrial chemical interest are as follows: Insecticides and fungicides, J. J. T. Graham, Bureau of Chemistry, Washington; fertilizers, R. N. Brackett, Clemson College, South Carolina; borax in fertilizers, W. H. Ross, Bureau of Plant Industry, Washington; preparation of ammonium citrate, C. S. Robinson, East Lansing, Mich.; nitrogen in fertilizers, I. K. Phelps, Bureau of Chemistry, Washington; potash availability, A. G. McCall, College Park, Maryland.

Important committees appointed were as follows: Vegetation tests on the availability of phosphoric acid in basic slag—H. D. Haskins, Agricultural Experiment Station, Amherst, Mass., chairman; C. B. Williams, W. B. Elliott, B. L. Hartwell and J. A. Bizzell. Committee to co-operate with A.S.T.M. on standards for and methods of testing agricultural lime—W. H. McIntire, Knoxville, Tenn., chairman; William Frear and F. P. Veitch. Committee on quartz plate standardization and normal weight for sugar—F. J. Bates, Bureau of Standards, Washington, chairman; C. A. Browne and F. W. Zernan.

OBJECTION TO OFFICIAL METHODS FOR PHOSPHORIC ACID DETERMINATION

H. P. Nelligan, of the American Glue Co., presented before the Association of Official Agricultural Chemists certain important objections to the present official methods of analysis for determination of phosphoric acid in commercial materials largely used as fertilizers. He stated his objections as follows:

The American Glue Co. produces dicalcium phosphate as a byproduct in the manufacture of osseine. This product is sold and valued on the market for fertilizer purposes according to its content of citrate soluble phosphoric acid as determined by the method prescribed by the Association of Official Agricultural Chemists. This method is not applicable to our product, which is a comparatively pure dicalcium phosphate. The official method was undoubtedly designed for a mixed fertilizer, and in all probability never more than 500 lb. of our product would be used in a fertilizer mixture. Now, in such a case, the charge to be weighed out for the determination of insoluble phosphoric acid would contain (in the mixture) only $\frac{1}{2}$ g. of the dicalcium phosphate, which would no doubt give full credit for all of the available phosphoric acid present. It is the consensus of opinion of all chemists who have done any considerable amount of work on this product that the present method is manifestly unfair, for when the material is mixed with other fertilizers it gives a higher availability in proportion than does the raw material, yet no provision has been made by the association to take care of this condition.

We have always been under the impression that the object of the Association of Official Agricultural Chemists was to secure uniformity and accuracy in the methods of analysis, yet the official methods in this case inflict an unjust penalty upon the American Glue Co. These conditions were brought to the attention of the

Association three years ago, and during this time the American Glue Co. has stood a considerable loss on this product.

We produce each year about 2,500 tons of this material. It is safe to assume that if the official method of analysis for this product was amended so that a 1-g. charge was used with 100 c.c. of ammonium citrate instead of the official 2-g. charge, we would gain in the vicinity of 2 per cent available P_2O_5 on all our production. The dicalcium phosphate is sold at so much per unit citrate soluble P_2O_5 . At the present market value, we stand a loss of between \$5,000 and \$6,000 a year on this discrepancy in the present method of analysis.

The referee of the association on available phosphoric acid in precipitated phosphates, H. D. Haskins, reported his investigations on this matter in the following language:

Your referee is convinced that the present official method for the determination of available phosphoric acid does not give full justice to this class of material and he would, therefore, recommend:

That the determination of insoluble phosphoric acid in precipitated phosphate be carried out according to the present official method for the determination of insoluble phosphoric acid in fertilizers with the exception that a 1-g. charge be employed and that a quality of filter paper corresponding to C.S. & S. No. 597 be used together with perforated platinum cone and gentle suction in the filtration of the citrate solution after treatment.

NEUTRAL AMMONIUM CITRATE SOLUTION

The composition and preparation of a neutral solution of ammonium citrate was discussed by C. S. Robinson. He recommends as a solution for use in the determination of phosphoric acid one which contains NH_4 and $C_6H_5O_7$ in the ratio of 1 to 3.794. He also recommends certain methods for the preparation of this solution which are the result of investigation as to the significance with respect to hydrogen ion concentration of solutions prepared by different methods. It is evident that that measure of neutrality is very important as affecting the apparent phosphoric acid content of this type of fertilizer material.

The committees of the association will study this subject further in collaboration with the industries affected.

Wisconsin University Revises Chemistry Work

A revision of the courses of the chemistry department of the University of Wisconsin has just been completed with the purpose of meeting a need for greater specialization in this profession. A greater number of elective college subjects outside of chemistry are required under the new ruling, as a part of the special courses, in order to give the student more cultural training. In the freshman year mechanical drawing has been made a required subject and mathematical chemistry is required in the sophomore year. In the general course industrial chemistry is required of all students.

Another new ruling is that at least one industrial trip must be taken during the course. The department also urges that each student obtain summer employment in his particular branch of chemistry so that he can bring to his theoretical studies the appreciation of their practical application.

During the coming year a general course, a course for industrial chemist, a course for food and sanitary chemist and a course for agricultural chemist are to be offered by the chemistry department. The courses for physiological chemists and for soils chemists have been dropped because of insufficient demand.

Special Service by Chemists' Club Library

Some time ago the Chemists' Club asked the co-operation of industrial chemical concerns in the support of a special service in the Chemists' Club library. This request met with a generous response and the library committee now announces to all who co-operated with the club that the services of Dr. M. A. Graham have been secured for this work. Dr. Graham will give her time exclusively to the answering of requests for special information, compiling of special reports and bibliographies, and will be available to render every possible assistance to employees of our subscribers in searching the literature. Work of this kind requires very broad chemical training, which requirement is well fulfilled by Dr. Graham. All work of this kind done for subscribers will be treated entirely confidentially. No charge will be made for work of this kind except in special instances where considerable time is required, in which case merely a nominal charge will be made.

Important Rulings on Petroleum and Natural Gas Passed in Canada

Two important orders in council have been passed by the Canadian Government. One provides that petroleum and natural gas regulations applicable to dominion lands shall be extended to certain portions of the forest reserves in order that an opportunity may be given to test these lands with a view to discovery. The other provides that for a period of five years after the date upon which the Minister of Interior shall declare that oil in commercial quantities has been discovered on crown lands, acquired under regulations governing such lands, the royalty to be exacted by the crown shall not exceed 5 per cent of the output of the well on sale of the product of the locations, nor be less than 2½ per cent, and for the following five years it shall not be more than 10 per cent nor less than 5 per cent. After the ten-year period it shall be 10 per cent.

This applies only to the Provinces of Alberta, Manitoba and Saskatchewan, and the Yukon and Northwest territories. In the other provinces the oil rights are vested with the provincial governments.

Chemical and Fertilizer Tonnage

Chemicals and explosives to the extent of 2,038,223 tons were carried on the Class 1 railroads of the United States during the quarter ended June 30. This is shown by the statistical compilation just made public by the Interstate Commerce Commission. This compilation shows the tonnage of seventy commodities which were transported on the Class 1 roads—those having annual operating revenues above \$1,000,000. These roads carry more than 90 per cent of all freight transported.

The tonnage of chemicals and explosives carried during the second quarter was somewhat greater than that during the first quarter, when it totaled 1,960,190 tons.

The fertilizer tonnage decreased decidedly during the second quarter. During that period 2,947,492 tons of fertilizer was handled by the principal railroads. During the first quarter the tonnage was 3,652,612.

The tonnage handled of some of the other commodities in which the chemical industry is interested is shown as follows in the report for the second quarter:

	Tons
Refined petroleum and its products.....	7,184,453
V. table oils	212,121
Sugar, sirup, glucose and molasses.....	1,485,118
Cotton seed and products, except oil.....	510,716
Crude petroleum	1,600,870
Pulp wood	1,396,186

Annual Meeting of the American Petroleum Institute

The convention of the American Petroleum Institute, which was held in Washington, Nov. 17 to 19, was significant principally because of the spirit of fraternity which was manifested. This was particularly striking to those acquainted with the antagonisms which have been assumed to exist between the independent operators and the representatives of the more highly organized companies. These interests now seem entirely disposed to work together to meet the common problems of their industry.

All of the officers and directors of the institute were reelected for the ensuing year. These officers are Thomas A. O'Donnell, president; S. Messer, vice-president; H. F. Sinclair, treasurer; R. L. Welsh, general secretary and counsel; C. C. Smith, assistant general secretary and treasurer.

Some of the important points brought out by the various speakers in their addresses were: That the demand for petroleum and its products is keeping pace with production and bears every promise of expanding in the future as rapidly as more crude can be supplied; the enormous demand for petroleum in America and the relatively smaller part our home production is going to play in the future necessitates going to foreign fields to supplement this demand; the necessity of foreign policy being changed so as to enable outside interests to help develop the oil resources for the good of all concerned instead of monopolizing the deposits for their own use; more freedom from governmental restrictions in the development of the oil industry by private individuals and corporations; the necessity of conservation of fuel oil as a means of power for our merchant marine and stimulation of further search for new sources of supply.

There was little of a chemical nature discussed. The group on Uniformity in Testing Methods, however, adopted the following resolutions:

Resolved, That the Group Conference on "Uniformity in Testing Methods" recommend that the American Petroleum Institute call together and arrange to secure the co-operation and co-ordination of all existing agencies and petroleum associations working for or interested in uniformity in testing methods; to arrange for a central referee testing laboratory, the prompt dissemination of information concerning standard methods of tests and research work looking forward to improved methods of test.

Rennerfelt Electric Furnace Installed at the San Francisco Mint

In order to meet the increased demand for cents and nickels a 1-ton Rennerfelt electric-arc furnace has been installed at the San Francisco Mint. The electric furnace replaces oil-fired crucible furnaces for the melting of stock for cents, the copper-nickel alloy used for five-cent pieces and also for the tin-zinc alloy which, with copper, forms the cent alloy. The furnace is of the three-phase type using 2½-in. graphite electrodes, and is hand-operated. It is expected to produce a 1,000-lb. charge in three hours. A 1-ton and a 1,200-lb. Rennerfelt furnace have been operating at the Philadelphia Mint on the same alloys and have effected considerable saving in the cost of production.

It is only recently that the use of cents has become common in the West. The tax on theater tickets, 6c. and 7c. carfare and the cafeteria created the demand, and with a supply available the use of cents has become customary in stores.

Clayburn Co., Ltd., Reopens Kilgarde Plant

The Clayburn Co., Ltd., manufacturer of building brick, firebrick, tiles and drain pipes, has reopened its second plant at Kilgarde, B. C. Both of the plants at Kilgarde and those at Clayburn are now working at full capacity and more than 150 men are employed. The company is sending its products as far as Montreal in one direction and San Francisco in the other.

Canadian Electro Leather Industries Organized

The Canadian Electro Leather Industries has been organized in Vancouver, B. C., and will erect a plant at McKay Creek to treat 500 hides weekly. The cost of the plant will be between \$30,000 and \$40,000. Electricity is said to play an important part in the tanning process. A similar plant is said to be operating successfully at Singapore, and the McKay Creek plant is to be constructed on the same lines.

Carnegie Institute of Technology Has Elaborate Coal-Mining Laboratory

The Carnegie Institute of Technology of Pittsburgh is completing the most elaborate coal-mining laboratory in America. The laboratory, which will be finished by the opening of the fall term, is located beneath the building of the division of science and engineering of the institute. The equipment comprises a full-sized coal mine—a model mine, except that it yields no coal—a mine locomotive and a full set of coal and metal mine machinery, that has been furnished by manufacturers. In addition to the mining laboratories proper there will be a completely equipped ore-dressing and coal-washing plant. It is purposed to extend the mine during the practice work of the students along such a plan that it can be utilized for carrying some of the steam and water pipes of the institute.

Steel Co. to Be Established in British Columbia

Coast Range Steel, Ltd., has been incorporated, with a capitalization of \$15,000,000, and head office at Vancouver, B. C. The provisional directors are H. J. Landahl, Fred T. Congdon, J. D. Kearns, John Stela and Montague Moore, all of Vancouver. The avowed object of the company is the establishment of an iron and steel plant in British Columbia. Arrangements have been made with the provincial government for a bounty of \$3 per ton on all iron produced from British Columbia ore for a period of two years, with the probability of renewal, though possibly at a lower bounty. The concern is said to be backed by British capital, and there appears to be some evidence of this being so, as two British engineers, C. T. Williams and Francis Percy, have been in the province for the last two months investigating the iron-ore resources.

Paper Company of Dallas to Make Paper From Cotton Linters

The Trinity Paper Mills of Dallas, Tex., is to engage in the manufacture of pulp and paper from cotton linters, of which there is over 200,000 tons produced annually. There has been but small use for this product since the different governments suspended the immense production of nitro-cellulose in 1918. Large stores of this stock are accumulating while the cotton oil producers are forced to remove at least 75 lb. of lint per ton of seed in order to have a successful oil recovery, and the oil millers could profitably remove

as much as 200 lb. per ton of seed, as the lint left on the seed absorbs oil. All of this 200 lb. of lint can be used profitably in paper making.

Briefly the treatment of cotton linters in making pulp suitable for high-grade paper is very similar to the treatment usually given rags. It is a soda process and the treatment of the stock offers no particular disadvantages over that of any other fiber now in use. It can be used successfully in the manufacture of several different grades of paper, such as book, writing, blotting, toweling, and in place of sulphite wood pulp in the manufacture of newsprint.

The company expects to have a pulp mill in operation at Commerce, Tex., in the near future.

Personal

FRANCIS L. ADAMS is now special inspector at the Jones & Laughlin Steel Co., South Side Works, Pittsburgh, Pa.

C. E. ALDEN is now with the Permutit Co., New York City, in its technical department.

Dr. GEORGE BORROWMAN, who recently returned from chemical investigations in Europe, has resigned from research work with Dr. J. E. Teeple, New York City, to enter independent practice in Chicago.

C. F. CARRIER, who has been taking a year's leave, has fully recovered his health and is now associated with the chemical department of J. Q. Dickinson & Co., Malden, W. Va.

EDWARD W. ENGELMANN, consulting research engineer of the Jackling porphyry properties, is in New York.

CLYDE L. FREAR has left the Merrell-Soule Co., where he had charge of the control laboratory, to accept a position with the U. S. Naval Experiment Station, Annapolis, Md.

JOHN M. HAYES, treasurer of the Utah Copper Co., Salt Lake City, has resigned and will remove to Los Angeles, Cal., at the end of the year.

J. H. MATTHEWS of Wisconsin University will address the Milwaukee Section of the American Chemical Society Dec. 3. His subject deals with photochemistry.

C. F. MILLSPAUGH, of the Field Columbian Museum, addressed the Chicago Chemists' Club on Tuesday, Nov. 23, on "Some Collections of Crude Materials and Their Relations to the Scientific Men of the West."

J. R. POWELL spoke before the Chicago Chemists' Club on Nov. 15 on colloidal clay, with special reference to the bentonite deposits in Wyoming.

Sir THOMAS KIRKE ROSE has been awarded the gold medal of the Institution of Mining and Metallurgy, the highest distinction in the power of the Council to bestow, "in recognition of his eminent service in the advancement of metallurgical science, with special reference to the metallurgy of gold."

FOREST RUTHERFORD, consulting metallurgist, New York City, has returned to New York after spending several months in Colorado on mine examinations and milling problems.

H. LIVINGSTON SULMAN has been awarded the Consolidated Gold Fields of South Africa, Ltd., gold medal and premium of forty guineas for his paper, "A Contribution to the Study of Flotation."

C. M. WELD, mining engineer, D. M. LIDDELL, chemical engineer and metallurgist, and P. H. LAZENBY, a civil engineer with wide experience in public utilities, have formed a partnership for practice as consulting engineers and economists under the firm name of Weld, Liddell & Lazenby, with offices at 2 Rector St., New York City.

JOHN ARTHUR WILSON, chairman of the Milwaukee Section, American Chemical Society, was in New York last week on business.

Current Market Reports

The Chemical and Allied Industrial Markets

New York, Nov. 29, 1920.

Tremendous resale pressure continued in evidence during the last week's activities and prices in several items suffered further recession. Inquiries, however, appear to be gaining more strength, but the differential is still wide enough between buyers and sellers to keep business quiet. Export orders were in evidence since the pronounced strengthening of foreign exchange. Consumers have adopted an ultra-conservative attitude even though producers are endeavoring to make prices attractive and real business is not passing.

In general the entire chemical movement was slow, with buyers content to operate only for actual wants. Sellers are still on the offensive so far as spot and near-by forwards are concerned, but the resistance is still relatively weak and the disposition seems to be to keep stocks as light as possible prior to the taking of inventory.

Solid caustic soda was offered in some directions at \$3.75 @ \$4 per 100 lb., which is a new low record for this movement. Trading was not much in evidence and buyers are looking forward to further recessions. *Bleaching powder* broke down with keen competition and selling was reported as low as 33c. per lb. in small drums. Large drums at the works were quoted at 4c. per lb. *Bicarbonate of soda* producers report a steady movement against outstanding contracts to consuming trade and are quoting 23c. per lb. f.o.b. works. Factors in *chlorate of soda* are holding the market at 10c. per lb. works and are readily working off their output through standing contract channels. Spot supplies are not heavy, although odd lots could be obtained at a fraction under producers' figures. *Cream of tartar* has shown no evidence of life in the past few weeks and spot supplies are heard as low as 43c. per lb., with very little trading at this figure. Spot material of *oxalic acid* was heard on the market at 19c. per lb., with buyers showing relatively no interest. The range was up to 22c. per lb., depending on quantity, brand and seller. Improvement to the extent of inquiries was noted in *cyanide of soda* and indications gave promise of some better business developing. Supplies seem to be well scattered among dealers. German cyanide was held at 23@25c. per lb., French at 24@26c. and American at 29@30c. per lb.

POTASH SALTS

The potash industry has developed into one of the leading factors in the chemical market as American producers, confronted with a severe shortage and an incessant demand for potash products previously imported, set about to solve this difficult problem.

Like all other chemicals, potash has seen some abnormally high prices and producers have reaped a tremendous harvest in the last few years. Gunpowder manufacturers and foreign merchants were flooding the American market with a continuous volume of orders and prices soared far above the normal mark. In the past few months, however, with the general depression in business circles and recent German importations, potash has been on a sharp decline. Germany has once more come into the domestic market as a competitor, but the consensus of opinion in chemical circles is that it will be some years before any real imports can be expected to reach pre-war figures or before prices will be materially lowered to affect American producers. At present, however, America is looking forward to a fair supply from Europe, since it has not yet become able to meet the increased consuming demand. It is also certain that the new Administration will provide methods in the form of a new protective tariff to safeguard domestic producers from any strong foreign competition. In short, it seems probable that it will be many years before our European neighbors will be in a position to produce enough permanent surplus stock

for the American market. In the meantime America will continue developing her own resources with the hope of becoming a self-sustaining industry.

The beginning of 1920 saw *bichromate of potash* the leading factor in the potash group. A shortage of chrome ore, transportation difficulties and strong foreign demand brought the price from 27c. per lb. in January to 42c. per lb. in May. During April leading producers announced a temporary discontinuance of production owing to inability to obtain raw materials. Speculators saw an opportunity to work the market and shot prices up from 30c. to 40c. per lb. Since June, however, a rapid decline has been noticed and material is now available at 21c. per lb. *Caustic potash* demand during the past year was accentuated in sympathy with all other leading chemicals. A wide demand was noted from soft-soap makers, who reported a large volume of orders on hand for all parts of Europe. Prices were on a sharp advance for this commodity during the first five months of the year, climbing from 25c. per lb. to 33c. per lb. Material can be obtained at present at 16c. per lb. The call for *chlorate of potash* from the match and fireworks trades kept the price very steady until the past few weeks. Large importations have weakened the spot market considerably, and even though dealers quote 15c. per lb., no real interest was shown by the consuming trade.

COAL-TAR PRODUCTS

The coal-tar products market has taken the attitude of a secondary factor in the chemical industry. It seems that readjustments will have to be completed in all allied trades before anything can be satisfactorily undertaken in this branch. On the face of things it might seem that the proper thing to do would be to start at the crude end of the game and state plainly that any revisions downward are practically impossible or else make them at once and relieve further uncertainty. On the other hand, it is argued that nothing would be gained until the position of the ultimate consumer becomes better understood as to the extent of his probable needs. Reports show that large numbers of buyers are in town, but what purchasing is being done seems to be limited to small quantities to fill in for the holiday trade only, and until demand and prices become more stabilized in the allied lines, factors in the crude and intermediate markets contend that readjustment in prices would fail to stimulate buying. Trading during the week followed the regular routine that has prevailed during the past few weeks. Small quantities of *H acid* are reported moving at \$1.60 per lb. *Benzylchloride* producers report the general market requirements as rather light, while the supply is of usual fair volume with prices quoted at 25@35c. per lb. Supplies of *dinitrobenzene* retain their steady tendency with the output generally held by first hands, and show the usual range of prices from 32c. to 35c. per lb. Demand for *aniline salts* is light and available supplies are free enough to keep the market easy and dealers offer spot supplies at 32@33c. per lb. Sales of *aniline oil* are limited only to small quantities, and while producers are still quoting 30c. per lb. resale material is held at 27c. per lb., with very little business even at the outside figure.

WAXES

The wax market has been quiet and featureless for the last few weeks. Export orders, that have been so common in this commodity, have entirely disappeared of late and hand to mouth business to domestic consumers is about the only business noted.

Beeswax continued dull, with offerings fairly liberal, especially in the lower grades. *Crude African beeswax* was offered at 20c. per lb. and it was intimated that round lots for shipment might have brought concession. *Brazilian beeswax* was quoted nominally at 28@30c. per lb. The higher grades of *Carnauba wax* are holding up well considering the routine nature of business. Brazilian markets were unsettled according to advices received in local circles, causing dealers to hold aloof. *Carnauba No. 1* was held around the 85c. per lb. level. *No. 3 North Country* was unchanged and closed at 25@27c. per lb. Scattered business is noted in *Japan wax* for immediate delivery at 19@19½c. per lb., indicating that the market is fairly steady. The

export movement that has characterized the *paraffine wax* market has taken a great slump and dealers are inclined, therefore, to offer their merchandise at surprising concessions. *Crude 124-126 m.p.* was quoted at 7½c. per lb., with very little response from consumers.

POTASH SALES

	Jan April	May July	Aug Sept	Oct	Nov.
Bichromate Potash,...	27 37c	42 37c	36 30c	30 26c	25 20c

The Chicago Market

Chicago, Nov. 26, 1920.

Without exception, every line of trade in the chemical industry reports continued inactivity and further depression of prices. Most advisers to the trade recommend extreme caution in buying, and this advice is being followed to such an extent that no factors are making engagements for supplies in excess of thirty days' requirements. Undoubtedly those concerns which have been existing on week-to-week supplies of chemicals will, when they figure the bottom has been reached, come into the market with some real buying.

Coal-tar products seem to occupy the weakest position as the result of heavy imports. Total importations of coal-tar products for the first nine months of this year is \$7,865,000, against \$4,710,000 for the same portion of last year. The Department of Commerce reports imports of chemicals, drugs, dyes, etc., for the period from Jan. 1 to Oct. 1, 1920, of \$165,527,000, compared with \$81,846,000 in 1919.

HEAVY CHEMICALS

Plentiful supplies of all commodities are in evidence, but buyers are content to look on. Price recessions seem to excite no interest, and it is doubtful if even radical and unjustifiable cuts would induce any heavy buying, as all chemical users seem committed to a policy of day-to-day buying. *Bleaching powder* of various grades and at various prices is offered in plenty. Quotations on spots cover a wide range, figures from \$3.85 to \$5.25 per 100 lb. being heard. *Soda ash* also is getting no rapid action even when offered at below 2c. per lb. It can be purchased as low as 1.90c. Spot *caustic soda* is offered from warehouse at \$4. Some sales are mentioned at as low as \$3.90. *Sal soda*, quoted about \$2 per 100 lb., is also weak.

Soda nitrite, under pressure of plentiful supply, is offered at \$7.35, but not much business is being done at any figure. Holders of stock show every disposition to shade prices. *Soda cyanide*, affected by importations, is freely offered at 22¢@23c. per lb. *Nickel salts*, with a dull market catching heavy supplies in second hands, is offered on the spot at 14c. for the single salts. Manufacturers' price is about 2c. higher on the pound.

Trade in *alcohol* is very quiet, producers being reported as holding large stocks of all grades. The only price change of moment has been in *denatured*, which is now offered at 82¢@85c. per gal. for 96 per cent. *Glycerine* quotations of 20c. per lb. for c.p. grade, drums extra, are ruling, with but light buying resulting. Dynamite grade is 17½c. or 19c., depending on whether you are a buyer or a seller.

Acids are equally dull, with only small transactions noted; 60 per cent pure *acetic* is offered at \$10 per 100 lb., *nitric* at \$8.25 per 100 lb. for 42 deg., *sulphuric* at \$21 per ton for 66 deg. and *pyrogallie* at \$1.92 in crystal form.

COAL-TAR PRODUCTS

Overstocked domestic markets, combined with heavy imports, are forcing price levels down, in spite of which but little interest is shown by buyers. *Phenol* has taken a slump to 10½c. per lb. for spot offerings and it appears that real money would shade this from 1c. to ½c. *Naphthalene* has suffered from large offerings of German goods and either balls or flakes can be had for 10c. per lb. or less. *Toluene* is weak and uncertain, quotations ranging in the neighborhood of 32c. per gal. *Benzene* alone is remaining fairly

firm at 37c. per gal. for the pure. Demand on this item is well maintained.

Intermediates in the hands of makers are firmly held, but second hands are plainly worried at the stagnant market and are eager to shade prices. *Aniline oil*, offered at 25c. per lb., faces few takers, and the *salts*, at 33c. are even in less demand. *Benzaldehyde* is down to 55c. per lb. for technical grade and *beta naphthol* is offered at 40c. or even less. *Phosgene* is in good supply and fair demand at 45c. per lb.

VEGETABLE OILS

The downward trend of the market is proceeding without interruption, and temperatures above the average for the season are helping it along. *Linseed oil* is offered in tanks at 80c. and in small lots from jobbers' stocks at \$1 per gal. Prime summer yellow *cottonseed oil* is quoted at 8c. per lb. in sellers' tanks. *Corn oil*, at 8½c. per lb. in tanks f.o.b. Chicago, excites no interest, and but little business is being done in *coconut oil* at 16c. per lb. in barrels out of stock. *Red oil*, in tanks, is quoted locally at about 9½c. per lb.

NAVAL STORES

Conservative buying is the rule locally, both buyers and sellers apparently feeling their way with caution. Reports of reduced activity in the various consuming industries offset to a certain extent the effect of the reported smaller available supply. Withdrawal of foreign buyers from Eastern markets has effected price reductions, but a study of conditions shows that a reaction would not be a surprise. Producers show no great desire to get rid of stocks. Local quotation on *turpentine* is \$1.29 per gal. in barrels, \$1.22 per gal. in tanks. *Rosin* is held at \$11.50@\$11.65 for all grades.

The St. Louis Market

St. Louis, Mo., Nov. 26, 1920.

A further slowing up of spot business is the only change to be noted in this market during the past two weeks. In this way the depression in other lines is making itself felt in heavy chemical demand, but producers state that their shipments on contract are practically normal and that they are renewing contracts satisfactorily. Evidently fears of the necessity of cutting production have been allayed as one of the largest heavy chemical producers is planning an increase in output. The prices which were established around the beginning of November are holding firmly and producers feel that they have them under their control and are able to keep them on a sound basis. The decline in spot business seems to indicate that buyers are staying as close as possible to their day-to-day needs and producers do not look for this situation to be relieved until the depression in other lines ends.

The demand for 66 deg. *sulphuric acid* remains slow but fairly steady and prices are being maintained at \$22 per ton, carload lots. Oil refinery demand is at a satisfactory level and little decline in the demand from this quarter is expected. Quietness also marks the 98 per cent *sulphuric acid* market. It is quoted at \$25 per ton f.o.b. works. The quotation on the 60 deg. *sulphuric acid* is \$16.50 per ton and 1½c. per lb. in carboys, with demand slow. *Oleum* is holding at \$28.50 per ton.

Demand for *muriatic acid* is dull, but producers have not very large supplies on hand and have the situation well in hand. The price is holding at 1½¢@2c. per lb. in carboys and \$25 per ton in bulk.

The demand for *sodium bisulphate* (niter cake) is steady and the advanced quotations noted two weeks ago are still holding. The quotations are \$7@8 per ton.

The *nitric acid* market is slightly more active and prices of two weeks ago hold good. Quotations are \$7 per 100 lb. for the 36 deg. test and \$10 per 100 lb. for the 42 deg. test. Standard mixed acid is quoted at 1½c. per lb. of sulphuric content and 11½c. per lb. of nitric acid. Inquiries show no decrease but orders have fallen off slightly.

No further advance has been noted on *zinc chloride*, for which demand is fairly strong. It is quoted at \$4.50 per 100 lb. There has been no change in the market for U. S. Government supplies of *phenol*.

The Iron and Steel Market

Pittsburgh, Pa., Nov. 26, 1920.

Steel production by the independents continues to decrease rapidly, while the Steel Corporation maintains its production rate, the divergence being due of course to the difference in order books, as to volume of business and price involved. Some estimates place the rate of independent mill operation at an average of less than 50 per cent of capacity, and many mills are operating much below that as regards ingots.

Chairman Gary of the United States Steel Corporation late last week issued another of the periodical statements that the corporation has no intention at this time of changing its prices. The Industrial Board prices were promulgated March 21, 1919, and at intervals since then expectations have arisen that the corporation would advance above that schedule, making it desirable for Judge Gary to issue a statement indicating that the expectations were unfounded. The latest statement, however, may be viewed also as a statement that the corporation will not reduce its prices.

Probably as a result of Judge Gary's statement the independent steel producers generally began today to quote the Steel Corporation prices on bars, shapes and plates, these prices being 2.35c. on bars, 2.45c. on shapes and 2.65c. on plates. On Wednesday a canvass of at least half a dozen large independents showed that they were quoting bars, shapes and plates all at 3c., so that the reductions today on the part of these independents are \$13 per net ton on bars, \$11 on shapes and \$7 on plates. Several independents, however, have for several weeks past been quoting prices at or near the Steel Corporation level on particularly attractive inquiries.

As to rails, however, the interpretation of the Steel Corporation statement is clear in the minds of the trade, that there had been no thought of a reduction, but instead some thought of an advance. The Industrial Board prices were \$45 per gross ton for bessemer and \$47 for open-hearth rails, and of late some independents have quoted as much as \$16 over these prices. The Steel Corporation had made large reservations for 1921, prices to be named not later than Jan. 1. It is related that the railroads fully expected to pay the corporation at least \$50 for open-hearth rails.

STEEL PRICES

In sheets the market continues to decline. Blue annealed sheets have been offered in all gages on the basis of 4.50c. for 10 gage, or \$19 a ton above the Steel Corporation price. Black sheets have been offered down to 5.50c., or \$13 a ton above the corporation price. Galvanized sheets are offered by one mill at 6.70c., or \$20 over the corporation price, although that independent may be alone in quoting under 7c.

The first sale of any semi-finished steel by an independent at the Steel Corporation price has just occurred, 6,000 tons for December, January and February being sold at \$48.40 delivered to a mill which has a freight rate of \$1.40 from Pittsburgh, this being equivalent to the Steel Corporation price of \$47 Pittsburgh. The trade has not ascertained who made the sale. Quotations on the inquiry ran up to \$60, one mill quoting \$60 Youngstown, equal to \$62.10 delivered, and another \$60 Pittsburgh, or \$61.40 delivered. As to sheet bars, however, it is predicted in some quarters that the Steel Corporation will recede to the Industrial Board price of \$42, its advance in September to \$47 having applied merely to certain contracts that involve a quarterly fixing of price.

PIG IRON

Bessemer and basic pig iron have receded \$2.50 in the week, being now available at \$37.50 valley for bessemer and at \$35 valley for basic. There was little temptation by way of inquiry to induce the declines. The basic decline appears to have been prompted chiefly by the offering of iron by steel works that normally consume their entire product themselves. Foundry iron remains nominally quotable at \$39 valley. The recession from the top prices reached late last August, while perfectly natural in a way, has been phenomenally rapid. The total recessions to date are \$11 in bessemer, \$13.50 in basic and \$11 in foundry. There is no doubt that iron will go below \$30, but the rest of the decline may be slower.

Naphthalene crushed, in bbls (250 lb).....	lb. .09 - .09
Naphthalene, flake.....	lb. .09 - .09
Naphthalene, balls.....	lb. .09 - .10
Naphthionic acid, crude.....	lb. .70 - .75
Nitrobenzene.....	lb. .12 - .15
Nitronaphthalene.....	lb. .40 - .50
Nitrotoluene.....	lb. .18 - .25
Ortho-amidophenol.....	lb. 3.20 - 3.75
Ortho-dichlorobenzene.....	lb. .15 - .20
Ortho-nitrophenol.....	lb. .75 - .80
Ortho-nitrotoluene.....	lb. .25 - .40
Ortho-toluidine.....	lb. .30 - .32
Para-amidophenol, base.....	lb. 2.35 - 2.40
Para-amidophenol, HCl.....	lb. 2.25 - 2.30
Para-dichlorobenzene.....	lb. .10 - .15
Paranitroaniline.....	lb. 1.10 - 1.15

Para-nitrotoluene.....	lb. 1.25 - 1.40
Para-phenylenediamine.....	lb. 2.20 - 2.35
Para-toluidine.....	lb. 1.85 - 2.00
Phthalic anhydride.....	lb. .60 - .70
Phenol, U. S. P., drums (dest.), (240 lb).....	lb. .08 - .10
Pyridine.....	gal. 2.00 - 3.50
Resorcinol, technical.....	lb. 2.90 - 3.00
Resorcinol, pure.....	lb. 3.75 - 4.15
Salicylic acid, tech., in bbls. (110 lb).....	lb. .35 - .38
Salicylic acid, U. S. P.....	lb. .40 - .45
Salol.....	lb. .85 - .95
Solvent naphtha, water-white, in drums, 100 gal. gal.....	gal. .30 - .35
Solvent naphtha, crude, heavy, in drums, 100 gal. gal.....	gal. .19 - .22
Sulphanilic acid, crude.....	lb. .32 - .35
Tolidine.....	lb. 1.45 - 1.50
Toluidine, mixed.....	lb. .45 - .55
Toluene, in tank cars.....	gal. .35 - .38
Toluene, in drums.....	gal. .38 - .40
Xylidines, drums, 100 gal.....	lb. .45 - .50
Xylene, pure, in drums.....	gal. .45 - .47
Xylene, pure, in tank cars.....	gal. .45 - .45
Xylene, commercial, in drums, 100 gal.....	gal. .37 - .38
Xylene, commercial, in tank cars.....	gal. .30 - .30

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....	lb. \$0.26 - \$0.27
Beeswax, refined, light.....	lb. .28 - .30
Beeswax, white pure.....	lb. .35 - .40
Carnauba, No. 1, (nominal).....	lb. .80 - .90
Carnauba, No. 2, regular (nominal).....	lb. .70 - .80
Carnauba, No. 3, North Country.....	lb. .25 - .26
Japan.....	lb. .19 - .20
Montan, crude.....	lb. .12 - .14
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb. .07 - .08
Paraffine waxes, crude, scale 124-126 m.p.....	lb. .07 - .07
Paraffine waxes, refined, 118-120 m.p.....	lb. .09 - .09
Paraffine waxes, refined, 125 m.p.....	lb. .09 - .09
Paraffine waxes, refined, 128-130 m.p.....	lb. .10 - .11
Paraffine waxes, refined, 133-135 m.p.....	lb. .13 - .14
Paraffine waxes, refined, 135-137 m.p.....	lb. .14 - .15
Stearic acid, single pressed.....	lb. .17 - .17
Stearic acid, double pressed.....	lb. .18 - .19
Stearic acid, triple pressed.....	lb. .22 - .23

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....	gal. \$1.90
Pine oil, pure, dist. dist.....	gal. 1.50
Pine tar oil, ref., sp. gr. 1.025-1.035.....	gal. .48
Pine tar oil, crude, sp. gr. 1.025-1.035 (tank cars) f.o.b. Jacksonville, Fla.....	gal. .35
Pine tar oil, double ref., sp. gr. 0.965-0.990.....	gal. .75
Pine tar, ref., thin, sp. gr. 1.080-1.060.....	gal. .36
Turpentine, crude, sp. gr. 0.900-0.970.....	gal. 1.25
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....	gal. .35
Pine wood creosote, ref.....	gal. .52

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl.....	280 lb. \$11.25 -
Rosin E-I.....	280 lb. 11.25 -
Rosin K-N.....	280 lb. 11.25 -
Rosin W. G.-W. W.....	280 lb. 11.50 - 11.75
Wood rosin, bbl.....	280 lb. 11.00 -
Spirits of turpentine.....	gal. 1.02 -
Wood turpentine, steam dist.....	gal. 1.00 -
Wood turpentine, dest. dist.....	gal. 1.00 -
Pine tar pitch, bbl.....	200 lb. . . . - 8.50
Tar, kiln burned, bbl. (500 lb).....	bbl. . . . - 15.00
Retort tar, bbl.....	500 lb. 15.00 - 15.50
Rosin oil, first run.....	gal. .70 -
Rosin oil, second run.....	gal. .73 -
Rosin oil, third run.....	gal. .90 -

Solvents

73-76 deg., steel bbls. (85 lb).....	gal. \$0.41
70-72 deg., steel bbls. (85 lb).....	gal. .39
68-70 deg., steel bbls. (85 lb).....	gal. .38
V. M. and P. naphtha, steel bbls. (85 lb).....	gal. .30

Crude Rubber

Para—Upriver fine (nominal).....	lb. \$0.22 - \$0.23
Upriver coarse (nominal).....	lb. .15 - .16
Upriver cauché ball (nominal).....	lb. .16 - .17
Plantation—First latex crepe.....	lb. .19 -
Ribbed smoked sheets.....	lb. .18 -
Brown crepe, thin, clean.....	lb. .16 -
Amber crepe No. 1.....	lb. .17 -

Oils

VEGETABLE

The following prices are f.o.b., New York for carload lots.

Castor oil, No. 3, in bbls.....	lb. \$0.14 - \$0.15
Castor oil, AA, in bbls.....	lb. .15 - .16
China wood oil, in bbls. (f.o.b. Pac coast).....	lb. .12 - .12
Cocanut oil, Ceylon grade, in bbls.....	lb. .14 - .14
Cocanut oil, Ceylon grade, in bbls (nominal).....	lb. .15 - .16
Corn oil, crude, in bbls.....	lb. .10 - .10
Cottonseed oil, crude (f.o.b. mill).....	lb. .06 - .07
Cottonseed oil, summer yellow.....	lb. .09 - .10
Cottonseed oil, winter yellow.....	lb. .11 - .12
Linseed oil, raw, car lots (domestic).....	gal. .83
Linseed oil, raw, tank cars (domestic).....	gal. .80
Linseed oil, boiled, car lots (domestic).....	gal. .85

Olive oil, commercial.....	gal.	2.75	—	3.00
Palm, Lagos.....	lb.	.09	—	.09
Palm, Niger.....	lb.	.09	—	.09
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.08	—	.09
Peanut oil, refined, in bbls.....	lb.	.15	—	.15
Rapeseed oil, refined in bbls.....	gal.	1.15	—	1.20
Rapeseed oil, blown, in bbls.....	gal.	1.25	—	1.35
Soya bean oil (Manchurian), in bbls N. Y.....	lb.	.09	—	.10
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.07	—	.07

FISH

Light pressed Menhaden.....	gal.	\$0.65	—	\$0.70
Yellow bleached Menhaden.....	gal.	.67	—	.70
White bleached Menhaden.....	gal.	.72	—	.75
Blown Menhaden.....	gal.	1.05	—	1.10

Miscellaneous Materials

Michigan

SAGINAW The Bd. Educ. plans to build a 3-story, 175x282-ft. school on Weadock and Park Sts. A chemical laboratory will be installed in same. Estimated cost, \$1,000,000. Cowles & Mutscheller, Chase Bldg., archts.

Minnesota

ANNANDALE The Bd. Educ. is having plans prepared for the construction of a 2-story, 110x151-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$250,000. C. H. Parsons, 600 Builders Exch., Minneapolis, archt.

EVLETH The Bd. Educ. will receive bids about January for the construction of a 3-story, 110x200-ft. vocational high school. A chemical laboratory will be installed in same. Estimated cost, \$750,000. J. M. Stearns, clk. W. T. Bray, 817 Torrey Bldg., Duluth, archt.

LONG PRAIRIE The Bd. Educ. has awarded the contract for the construction of a 2-story, 75x160-ft. high school to the Carlsted Bros., 512 Builders Exch. Bldg., Minneapolis. A chemical laboratory will be installed in same. Estimated cost, \$86,692.

Nebraska

NORFOLK The Bd. Educ. had plans prepared for the construction of a 2-story high school. A chemical laboratory will be installed in same. Estimated cost, \$150,000. J. C. Sutt, archt.

New Jersey

GLEN ROCK (Ridgewood P. O.) The city will receive bids in March for the construction of a sewage disposal plant, etc. Estimated cost, \$300,000. H. J. Harder, engr.

PASSAIC The Newport Chemical Wks., Inc., 168 River Drive, plans to build a warehouse. R. W. Willmer, secy.

New York

OSWEGO The Bd. Educ. plans to build a 3-story, 200x261-ft. high school on Glen St. Laboratory equipment will be installed in same. Estimated cost, \$150,000. J. A. Randall, S. A. & K. Bldg., Syracuse, archt. and engr.

SHEEPSHEAD BAY C. A. Benoit, Jerome Ave., has awarded the contract for the construction of a factory on Jerome Ave. to the Gotsch Eng. Corp., 103 Park Ave., New York City. Estimated cost, \$150,000.

Ohio

DAYTON The Bd. Educ. plans to build a 3-story high school on Summit St. A chemical laboratory will be installed in same. Estimated cost, \$750,000. Schenk & William, Mutual Bldg., archts.

Oklahoma

MIAMI The city has awarded the contract for the construction of a sewage disposal plant, etc., to James & Shon, City Hall. Estimated cost, \$111,000.

Pennsylvania

HAZLETON The United Filters Corp. is building a plant, including several buildings. Filters for chemical food and mining industries will be installed in same. C. M. Stanley, chief engr.

West Virginia

HUNTINGTON The Fordette Engine Co. plans to build a plant for the manufacture of gas engines. Plans will probably include a foundry for castings, machine shop and assembling plant. Estimated cost, \$100,000.

Quebec

THREE RIVERS—The Three Rivers Pulp & Paper Co. has awarded the contract for the construction of a pulp and paper plant to William I. Bishop Co., 10 Cathcart St., Montreal. Estimated cost, \$500,000.

QUEBEC CITY—P. A. Beaulieu, 37 Boulevard St., will soon receive bids for the construction of a brass foundry including equipment. Estimated cost, \$69,000.

New Publications

MECHANICAL ORE SAMPLING IN MONTANA, by H. B. Pulsifer. Published by the State School of Mines, Butte, Mont.

RECENT INCREASES IN THE PRICES OF PETROLEUM AND ITS PRODUCTS, published by the American Petroleum Institute, 15 West 41th St., New York City.

ANNUAL REPORT FOR THE YEAR 1919, published by the Bureau of Mines, State of Colorado, Denver, Col.

THE CHICAGO GEOGRAPHIC SOCIETY, Harry P. Pearson, president, is making plans for the founding of a geographic magazine defined as "an organ of discovery and interpretation disclosing man to man and unifying his family in the exchanges of commerce." The trade and banking interests of Chicago are in favor of this movement because of its value to commerce.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deshler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29, 1921.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its winter meeting at New Orleans, Dec. 6 to 9. Headquarters will be at the Hotel St. Charles.

AMERICAN PHYSICAL SOCIETY will hold a meeting Nov. 27 at the Case School of Applied Science, Cleveland, and the annual meeting, beginning Dec. 28, at Chicago, the latter being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS' 1920 annual meeting will be held in the Engineering Societies Building from Dec. 7 to 10 inclusive.

COMMON BRICK MANUFACTURERS' ASSOCIATION OF AMERICA will hold its annual meeting at the Hotel Pennsylvania, New York City, Jan. 31 to Feb. 1.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at the Statler Restaurant, Newark, N. J., the second Monday of every month.

TAYLOR SOCIETY will hold its annual meeting Dec. 2, 3 and 4 in the Engineering Societies Bldg., New York City. The meeting of Dec. 3 at 8 p.m. will be of special interest to metallurgists. The subject will be "The Long Day in the Steel Industry."

The following chemical societies will meet at Runford Hall, Chemists' Club, New York City, as follows: Dec. 10, American Chemical Society, joint meeting with Society of Chemical Industry, American Electrochemical Society and Société de Chimie Industrielle; Jan. 7, American Chemical Society, Jan. 14, Society of Chemical Industry, Perkin Medal award; Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society, Nichols Medal award; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

In the Interest of Education in Mathematics

IT IS PROFITABLE in more ways than one to study the reports of the Rockefeller Foundation and the General Educational Board. The literary style of President VINCENT of the Foundation, whereby, in the simplicity of consummate art, he tells, in the fewest possible words, of their herculean efforts in battle against disease and for health all over the world, is an inspiration in itself. And again, to know that while so large a part of the world seems to have lost its ideals and to have gone loose in thinking and in character, there are those who are diligent in well-doing without trying to make a fuss about it is a still greater inspiration. In his report of the General Educational Board Dr. BUTTERICK explains their activities with the greatest praise for the generosity of others, but with such modesty for the Board's own immense disbursements as to give the impression that they really had to do it and that he hoped you would excuse them for having to acknowledge it.

One item in explanation of an appropriation for a committee of the Mathematical Association of America deserves mention here. A great many of our chemists and chemical as well as other engineers are short in their mathematics. Even among those who have studied and have passed their examinations, the understanding and the philosophy of mathematics is often lacking. Mathematics is too often taken like Latin to be studied "to train the mind" and then forgotten. By far too much is known by formula only. Now this committee composed of professors and instructors from colleges and secondary schools present a report which is reprinted in full in the report of the General Educational Board, and it is well worth reading. They believe that both in colleges and secondary schools the mathematical curriculum is in need of reformation. It should be adapted to the needs of the world of today and tomorrow instead of the world of yesterday. It is held that secondary school mathematics may prepare the student for his life work as well as for college courses without lowering the standard of scholarship. In regard to algebra, for instance, they say: "Our elementary algebra is, in theory and symbolism, substantially what it was in the seventeenth century. The present standards of drill work, largely on non-essentials, were set up about fifty years ago. The few lines of application of algebra to nominally practical questions found in our college entrance examinations are mere variants of problems that are centuries old and often represent only remotely any real conditions of today. A considerable number of teachers, both in the secondary schools and in the colleges, believe that the amount of time spent by pupils on abstract work in difficult problems in division, factoring, fractions, simultaneous equations, radi-

als, etc., is excessive; that such work leads to nothing important in the science, and adds but little to facility in the manipulation of algebraic forms." They believe that the more difficult and abstract portions of such work could be replaced by work of a much more profitable nature, such as the real uses of algebra, the applications of intuitive geometry, modern methods of computation, and the significance of trigonometry. Among specific elementary topics which have of recent years been suggested and whose availability in this connection should receive careful and open-minded consideration may be mentioned the mathematics of business and finance, the graphic representation of facts, mechanical drawing and perspective, elementary notions of statistics, the use of logarithms (and of tables in general), the slide rule, elementary principles of surveying with field work, etc. It is also felt by many that, just as the mathematical work in the schools has in the past been enriched by the continual introduction of principles previously regarded as too advanced, the time has come to give careful consideration to the question whether in the more advanced secondary school courses the work could not be made more valuable, more vital and more significant by the introduction of the elementary principles of analytic geometry and calculus, and of projective geometry. It is urged that the elementary ideas and processes of these subjects are less difficult than some of those now included in our courses in advanced algebra and solid geometry, and much more interesting and significant.

"It is urged by many friendly critics that, instead of giving a student a good all-round idea of what mathematics means and of its general range of application, our present secondary school courses are too abstract, often uninteresting except to the mathematically inclined, and not as valuable as they might be as an aid to college work in general or to life work for those who enter at once into their careers. These are not the opinions of the extremists in the schools of education; they are the opinions that are held by a large number of college professors and secondary school teachers. They are not the opinions of destructionists, but of those who have well-defined ideas of a modern, living, scholarly course in mathematics to replace what they believe is rapidly becoming obsolete."

There is still more to the same effect, and we wish we had space for it. Suffice to say that the enlightened teachers believe that they can begin mathematics in secondary schools as a live study, and by extending it into the first two years of college courses, give the subject that reality and vitality to which it is entitled.

We congratulate the teachers on the support that they are receiving in this good work and we congratulate the General Educational Board on its wisdom. It looks like light ahead.

Patents Viewed As Contracts

SOME months ago, in our issue for Sept. 22, 1920, we published an article by CHESLA C. SHERLOCK on "The Value of Patents." The author made an admirable presentation of the position of the patentee as far as his monopolistic powers are concerned. He quoted one court as saying, "Within his domain he [the patentee] is czar." There is, however, another important phase of the matter which should not be overlooked—namely, the contract relation of the patentee to the public. By very reason of the fact that the patentee is czar within his domain, and because of the monopolistic powers conferred upon him, "the acts of legislatures which prescribe the limit and conditions of the patent privilege and the decisions of the courts in interpreting and applying such legislative acts relate to its contract character alone." Our authority is found in section 41 of Robinson on Patents.

In other words, a patent is primarily a contract between an inventor and the public, a contract by the terms of which the patentee is obliged distinctly to state and clearly point out in exact terms just wherein his invention lies and of what it consists. This duty to the state is explicitly imposed upon the patentee. Curtis says: "The truth is, a patent should be construed as what it really is, in substance—namely, a contract or bargain between the patentee and the public upon those points which involve the rights and interests of either party. These points relate to the extent of the claim and to the intelligibility of the description for the purposes of practice."

Courts and legal writers in treating this subject have consistently recognized the principle that patent law rests upon a contract basis. Hence, because of the broad—not to say monopolistic—character of the grant to the patentee, he is held by the courts strictly to the scope of his patent as distinctly claimed and clearly pointed out in the claims.

Doctor, Teacher, Chemist, Preacher

IN THE *Transactions* of the Institution of Mining and Metallurgy of Great Britain for the years 1917-18 there is a necrological note of interest. It refers to one of their members born in Canada in 1837, the son of a Canadian surgeon. As a young man the late member planned to follow his father's footsteps, studied medicine in Canada and Germany, but on returning to Quebec he became professor of chemistry at Morrin College, Quebec, instead of practicing his avowed profession. In the end neither medicine nor chemistry could hold his attention against what seemed a greater call, for he returned to Europe, this time to Scotland, where he matriculated and took the course in theology at the University of Edinburgh. In 1875, when he was thirty-eight years of age, he received his license to preach in the Presbyterian Church. He was not ordained in any pastorate, however, because just at that time his father's affairs, owing to unfortunate investments, called for his immediate presence in Canada again. He therefore returned and addressed himself to the problem of saving his father's property, but in order to provide for his own sustenance he became superintendent of an insane asylum, thus reverting in part to the practice of medicine again. Now, among the old doctor's investments that had gone wrong was the Harvey

Hill copper mine in Quebec, which could never be developed into a great success—but it gave the junior doctor-clergyman both interest in and experience on the subject of copper mining and the treatment of copper ores. His work along this line led to his engagement, as a man of forty, to become superintendent of a chemical copper extraction plant in Pennsylvania where Western matte was treated. In 1880, being then forty-three years of age, he went West to pay a visit to a recently opened mine in Arizona, where he recognized a great future for the industry. Then he returned East and interested some of the partners of a leading metal firm in the enterprise, but endured four or five years of great uncertainty and anxiety before the tide turned. After this there followed nearly forty years of immense personal and professional success in the development of the American copper mining and smelting industry, in which he was recognized as a great leader. The metal firm to which we refer was PHELPS, DODGE & Co., and the man whose history we have been sketching was none other than the late Dr. JAMES DOUGLAS.

An Appropriate Time For Investigations

WHEN times are good and material costs are low, it is easy to make money in industry. The real test of operating efficiency comes only when the operating margin is small or when costs advance sharply with reference to market demands for products. During the war period (and no economic discussion can fail to mention the war) chemical industry grew like Jack's beanstalk of fairy-tale fame. In many cases expansion at any cost or even with very poor efficiency represented a gain; but in normal times these low efficiencies are, of course, not at all acceptable.

With increasing complexity of industrial conditions during readjustment, the management of chemical industry is watching much more closely every detail of plant performance. It is a fine time to get out all the old operating records and analyze them in a way that the rush of production even beyond plant capacity forbade during the several years of war-time stress. These records, which perhaps were kept in a more or less perfunctory manner, now take on increased importance; from them in many cases it will be feasible to determine the relation between operating conditions and plant efficiency. Formerly, capacity output governed; now, plant efficiency is the determining factor in success. Even though in the past the chemical staff or the engineer of tests has largely been regarded as a necessary evil set by the management to spy upon the operating force, it will be worth while to see what this chemist or engineer of tests has to show.

Perhaps some of the research-laboratory recommendations for "improvements" in process can also be tried out most successfully at a time like this. Such trials frequently result in temporary interruptions of process, small amounts of material spoilage, or temporary reduction in output. The possibility of such losses or reduced speed of operation cannot be risked during times of large demand for output. But when there is a tendency to reduce stocks and to slow up operation to permit this, the time is particularly appropriate for these trials; and if the trials result in improved efficiency, in increase of output, or in decrease of costs, there is no time when such fortunate result is more welcome.

Engineering Reports Partisan and Impartial

IDEAL engineering reports are in effect miniature court decisions. The evidence is first arranged, the arguments are presented, and finally an engineering judgment is rendered." Thus one of the well-known consulting engineers of Chicago writes in his contribution to a discussion of the function and make-up of engineering consultants' reports. The same communication goes on to discuss how material should be treated by the engineer who makes the report, giving splendid suggestions on many points. But one point is not raised in this discussion—as to the attitude of the executive or board of directors for whom the report is prepared.

Facts are often uncomfortable things and judicially minded decisions and advice sometimes are disappointing. Nevertheless, when a consultant is engaged great pains should be taken that he is given full opportunity to get the facts and render to the best of his ability an absolutely impartial report or finding. To insure this is a part of the responsibility of the executive or board for whom the report is being prepared.

An outside investigator or adviser, unless unusually tactful or of unusual fame and ability, is likely to be received in anything but a friendly way by the operating staff whose work is under scrutiny. The lot of a consultant who is to advise as between two recommendations of the staff is particularly unhappy because of these factors. However, much of the possible good from expert assistance is lost unless some executive means be found to give the whole truth as a basis for recommendations. The executive should not be satisfied with a report based upon an investigation which has been in any way hampered to prevent such judicial consideration of all important pertinent factors.

There are, of course, many occasions upon which a consultant is engaged to assist in controversial matters as between a company and the authorities, or a company and some other commercial agency with which it happens to have legal or commercial difficulties. A report prepared by a consultant or with his assistance for public use and partisan purposes is, of course, proper in such circumstances. The consultant does not expect to emphasize both sides of the question, but will limit himself to the presentation of the points favorable to his client, which he will set forth honestly and as effectively as circumstances permit. For such work the consultant becomes in effect an advocate and takes on himself all of the responsibility and privileges of the attorney advocate, except that he usually limits his effort to the technical field.

This same attitude cannot successfully be assumed in reports prepared for the assistance of executive officers. For such latter purposes a discussion of both sides of any case, setting forth the strong points for and against the decision finally reached, is most satisfactory. The executive is entitled to know the evidence on both sides. Indeed, the final recommendation of the expert is strengthened by a frank presentation of the best arguments which may be advanced against his findings, even though the final recommendation be a definite judgment. The executive who receives such report is fortunate, for he can feel sure that his adviser has taken into account both sides of the question and has not simply undertaken to present convincing arguments in support of preconceived ideas.

The Regulation Of Immigration

THE Welty immigration bill introduced in the House of Representatives May 22, 1920, receives strong support in various quarters and is likely to constitute a live issue in Congress. Very briefly stated, its object is to regulate immigration from time to time by a flexible system administered by a board to be composed of an appointed member, who shall be chairman, and the Secretaries of State, Labor, Commerce, Agriculture and Interior. Immigration is to be considered by ethnic groups and the volume of each regulated according to assimilability and the industrial needs of the country.

It is not calling labor a "commodity" to say that the scheme is of the same order with a tariff system which seeks to encourage the importation of materials we need to import and aims to exclude materials not needed. With this fact in mind, and noting the widely divergent interests that have been represented in tariff discussions, it becomes obvious that a tremendous responsibility would have to be borne by the contemplated Immigration Board. The proponents of the bill undertake to depict the admirable results that would follow its enactment. The bill certainly aims to handle the matter of immigration in a scientific and practical manner and thus it is wholly novel by comparison with immigration legislation of the past.

The bill is naturally to be considered on the premise that there are certain objections to immigration. Those workers who object to immigration do so on the ground that they do not wish to be diluted, and do not wish the standard of employment to be reduced. The bill provides that the Immigration Board shall base its actions upon "the maintenance of American standards of living and wages," and in this respect again it becomes merely a question of whether the board functions perfectly. As to dilution, it is plainly the purpose of the proposed scheme to encourage the immigration of classes of workers we particularly need. It has been made quite plain by developments in recent years that the workers we have do not gravitate toward the various employments in the proportions that the public as a whole desires. The people in the cities insist that too many boys leave the farms. The consumers of coal insist that not enough men want to make coal mining their work, and so on and so on.

One can hardly doubt that the employment preferences of the people are not distributed in the proportion that would be best for us as a whole. If we can improve the analysis by increasing the percentages in certain lines, we should do so. If there are objections to the Welty plan on the part of groups of workers whose percentage has been tending to diminish below the proper level for the good of all, such objections should not be considered. For years there has been much preachment that we should make one occupation or another more comfortable and attractive whereby men would be moved to change their minds and take up that class of work. There has been very little success along this line. The main thing we have done is to bribe men, and that does not work well. The men are dissatisfied and seek constantly to have the bribe increased. If an ethnic group can be found that like the kind of work we do not like, it certainly would be a good plan to encourage people of that group to come and do the work. Would that not be much better than bribing an unwilling worker?

British Chemical Industry

(FROM OUR LONDON CORRESPONDENT)

London, Nov. 13, 1920.

WITH the passing of the coal strike the demand for chemicals has improved, particularly from the textile and other industries of prime importance. Nevertheless, prices remain steady, partly owing to the unsatisfactory condition of an export trade suffering from adverse exchange conditions, but mainly because the recent "shake-out" has done much to stabilize markets and to bring market prices within reasonable distance of actual manufacturing costs. The question of transport generally and the alleged unfair discrimination of the railway companies against the products of the chemical industry are receiving considerable attention and a new trade paper is to deal solely with this subject and with that of "freight exchange," which aims at the reduction of wasted "return empty" journeys. Distances being relatively small in this country, chemical manufacturers are increasingly adopting road transportation, and this tendency has been accentuated by the policy of the railway companies.

GOVERNMENT DELAYS RESTRICTIONS ON IMPORTED DYESTUFFS

For some time past the daily and technical press have been inundated with articles, often apparently inspired by those chiefly affected, emphasizing the importance of maintaining the dyestuff industry on an adequate scale, and explaining *ad nauseam* its relation to chemical warfare. From the national point of view the importance of being prepared in a military sense is admitted, but the average business man has realized that compared, for instance, with the maintenance of supremacy in the cotton and piece goods trade, the value of the home dyestuffs industry *per se* is almost negligible. At the same time the government definitely committed itself, when the prospectus of the British Dyestuffs Corporation was issued, to protect the industry from German aggression, and it will be remembered that the proclamation prohibiting importation except under license was vitiated by the "Sankey judgment." A year having elapsed during which German dyes have been entering freely in ever-increasing quantities, pressure is being applied on the government to redeem its pledge by immediate legislation. It was intended to include dyestuffs in the so-called "dumping bill" which was to protect other "key" industries such as glass, etc., but as the measure is a highly contentious one as far as the other key industries are concerned, immediate and separate legislation in regard to dyestuffs seems essential if the British dyestuffs industry and the interests of its shareholders are not to be seriously jeopardized. It seems probable that the government will agree, but there is grave misgiving in regard to the matter in the cotton trade, which will naturally be the loser. It is rumored that the Board of Trade will now summon a conference representative of all interests concerned in order to enable an agreed measure to be laid before Parliament, and such a course would probably solve the difficulty.

DYESTUFF MERCHANTS DEMAND EXPORT FACILITIES

The question of dyestuff exports and re-exports is closely bound up with this matter, because, as previously mentioned in these articles, there is a growing tendency among manufacturers, and dyestuff manufacturers are

a good example, to appoint their own distributors and to eliminate the merchants wherever possible by restricting supplies to them for the export trade. Merchants are now demanding price facilities for the export trade at least equal to those of manufacturers' agents and a scheme has also been drawn up to facilitate re-export of foreign dyestuffs from bond (with reasonable customs safeguards). As regards export, it is pointed out that rather than lose the valuable foreign and particularly Eastern trade connections secured in the past, the merchants would sell German, Swiss or U.S.A. dyestuffs in foreign markets in competition with the British products, which under present conditions would probably lead to reduced exports and to unemployment in the industry. Now that the merchants have at last formed a really representative association, there is a better prospect of their interests being safeguarded and of a compromise fair to all parties being agreed upon.

PROF. SODDY CONDEMNS GOVERNMENT RESEARCH POLICY AND CHEMICAL WARFARE SCHEME

Much valuable knowledge has admittedly been accumulated during the war and since by government departments and research associations subsidized by the government. It has been agreed that discoveries made with the aid of public funds should be made available, under proper conditions, for the public advantage, but it is notorious that in many cases these results and data have been sold or transferred to the great business interests, and where publication was made, it was only on a restricted scale. This is characterized by Prof. Soddy as unfair competition. At the same time he advocates increased use of the scientific and technical faculties of the universities to supplement the work of the research associations. Writing to *Nature*, Prof. Soddy complains that the committee to be constituted for chemical warfare and research is to submit in advance to the official secrets act and protests that scientific workers should not be called upon to prostitute science in times of peace to develop a mode of warfare which has not been legalized by civilized nations.

PROSPECTS OF ELECTROLYTIC IRON

The experimental manufacture of articles by electrodeposition of pure iron has been proceeding for some time at Grenoble, France, and simultaneously by other interests in this country. The difficulties due among other things to the occlusion of hydrogen seem now to have been overcome, and important developments are foreshadowed in regard to the use of electrolytic iron in the electrical industry, the manufacture of heating coils and radiators (sometimes coated with cadmium) and the economical substitution of iron for brass and the like in one-piece containers. This industry should be of special interest to American users, as cheap power is of importance for its successful development.

PERSONAL

Prof. C. S. Sherrington, of the University of Oxford, is to be the new president of the Royal Society.

Sir James Dobbie has retired from the post of Government Chemist.

Dr. O. Kamm, of Illinois University, has been appointed director of the chemical research department of Parke, Davis & Co., manufacturing chemists, of Hounslow and London.

Readers' Views and Comments

Engineers in Governmental Functions

To the Editor of Chemical & Metallurgical Engineering

SIR:—The war has thrown a new light upon several phases of the nation's political, social and economic life, emphasizing the need for readjustment of traditional administrative practices in public affairs in the interest of economy and conservation of resources. Long before the war there was a growing consciousness of the inadequate functioning of state and federal departments which in their nature were largely, or wholly, technical and therefore should be under the direction of trained and experienced engineers in order to obtain the most beneficial results in the interest of the public and for the money expended. Up to date the idea prevailed with the appointing power that lawyers and politicians had a prior claim upon administrative ability of whatever kind.

Of late the engineering fraternity has called attention to the inadequacy of lawyers and politicians assuming directive functions in matters for which they were not trained, with consequent wasteful use of public money, however honest the administration may otherwise be. The generally accepted reason for excluding the engineer from higher administrative functions in public service is that lawyers and politicians are by training and occupation better fitted to understand and to deal with the larger social needs of the public and to make public sentiment amenable to the requirements of governmental control. These broader, what might be called popular, qualifications are, it is claimed, not possessed by the engineer, who, however valuable as a professional man, is not trained to deal with the people and their social adjustments.

In the United States several factors have combined to give plausibility for preference of considering laymen better fitted even for technical administrative functions than professional engineers and technical men.

First, the engineer is only a comparatively recent arrival in the family of social and economic forces controlling the welfare of the public. Time is not so far distant when the surveyor was recognized as the engineer of his day and he performed the functions of an engineer in pioneer days. During all the evolutionary period there were only three socially and economically recognized professional classes—the lawyer, the doctor and the minister. What wonder then if the lawyer, as the representative of property right and law regulating the daily activities of the public, should be considered the natural incumbent of public administrative office?

Second, in a democracy the politician naturally occupies an exalted popular position in the community and is therefore considered suitable for administrative functions.

Third, the engineer represents the essentially economic side of public affairs, and the great wealth of natural resources in the United States has helped to produce wasteful, careless habits with the people, producing a natural antipathy and lack of understanding of the teachings of economy and conservation by the engineer.

The discoveries of science are enabling mankind to make generous use of the forces of nature for its own benefit, and the engineer is the learned and trained interpreter of these natural forces. If it is the lawyer's business to uphold positive law and to cultivate jurisprudence in order to maintain a state of public justice, just so is it the business of the engineer to cultivate the natural sciences in order to maintain a state of mental and physical welfare by means of scientific sewerage, lighting, water supply, sanitation, bridging, road building, transportation safety appliances, etc., without which the people could not live in a state to make them receptive for the benefits of legal, medical and spiritual ministrations according to the modern standard of civilization. Why then should the engineer not be considered competent at the present time and in the future, without interference by the lawyer or politician, to be at the head of the administration of those departments of public business which are engineering functions primarily and subjects of legal interpretation only secondarily?

When it comes to the application of social justice in public affairs the engineer is certainly equal to the lawyer and politician in that respect. Every well-educated engineer, of sufficient breadth of mind and experience in the management of private enterprises, should and would be competent to direct state or federal undertakings of a similar nature with greater advantage to the public interest than non-technical men who, because of their lack of technical training and experience, are frequently guided by the bureaucratic traditions of their office, with consequent waste of time and money.

If it is the purpose of social economy to make use of the mental and material resources of the country to best advantage in order to create a maximum of happiness, contentment and confidence in public institutions among the population, it is the modern engineer more than any other professional man who comes nearest to fostering and promoting this desirable purpose.

While the immediate results of the engineer's activities are of a tangible economic and commercial nature, in a larger sense these activities involve the ethical, the moral and the æsthetic life of the people because the conscientious execution of his activities by the engineer involve the ethical qualities of his sense of duty and responsibility to himself, to his client and to the community and the public at large.

On the other hand, to the degree this ethical sense of duty and responsibility toward his fellow citizens and to his country is developed among the people the more the conscientious and scientific work of the engineer will be appreciated and insisted upon for the material and moral benefit of the individual as well as of the public.

PAUL KREUTZPOINTNER.

Altoona, Pa.

Although there has been increasing recognition recently, especially in the federal departments, of the importance of technical specialists as administrative chiefs in technical work, there still is opportunity for increasing this tendency. There probably is only one need for limitation of the tendency to appointment of

technical men to administrative work for which they are particularly fitted. This is the result of the very limited number of such men who are available in comparison with the large demand for strictly technical service at the present time. An undue tendency to place technical workers in administrative function would, therefore, perhaps be an unfortunate factor, serving only to increase the shortage already acute of experienced, capable scientific and engineering investigators and consultants.

Changes in Cyanamide When Mixed With Fertilizer Materials

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your issue of Oct. 6 there appears a report on the program of the Fertilizer Division of the American Chemical Society as carried out at the recent Chicago meeting. The great industrial significance you attached to the paper of R. N. Harger, of the United States Department of Agriculture, has created considerable interest among fertilizer manufacturers, a viewpoint which Mr. Harger did not take in the actual paper as officially published.

The title of the paper in its official form is not "The Changes Taking Place in Cyanamide When Used in Mixed Fertilizers," but instead "The Change Taking Place in Cyanamide When Mixed With Fertilizer Materials."

Mr. Harger dealt only with laboratory mixtures of certain fertilizer materials and not with the commercial fertilizers as found on the market, as he distinctly emphasizes, and his conclusions were most carefully drawn and limited to the exact conditions surrounding his laboratory work. Since these conditions are different from those existing in the ordinary fertilizer plant, Mr. Harger in his official publication was careful to limit his conclusions to apply only to his laboratory work and not to the mixing plant.

Mr. Harger further did not carry out his work following the recommendations made by the manufacturers of cyanamide for the guidance of fertilizer mixers and as represented in the practice of the fertilizer plants, and since your report did not closely follow the details of Mr. Harger's procedure but rather implied the reverse, there has arisen in the minds of the mixers a natural question of doubt after reading your report.

I am certain you are desirous of correcting this erroneous impression created by the article in your journal and of presenting to your readers the true facts in the case as officially published by Mr. Harger. At the same time I believe you would be interested in calling the attention of your readers to the fact that the reactions described by Mr. Harger do not take place in ordinary commercial fertilizers when proceeding under recommendations for the use of cyanamide, as published by this company, and that such fertilizer mixers need not concern themselves about the presence of dicyandiamide in their mixtures, as such does not occur. Cyanamide is an extremely reactive substance, which on mixing with acid phosphate in the prescribed quantities is for a very large part converted into various ureas and in smaller part to ammonia and ammonia salts. When mixed with the ordinary ammoniated base which forms the bulk of the mixed fertilizer tonnage cyanamide reacts with the amino acids to form complex organic compounds, which so far as they have been isolated and studied are of excellent fertilizer value. Dicyandiamide cannot be produced in the presence of these ammoniated base compounds. In the ordinary acid phosphate mixture it can be produced only in extremely

small quantity by a direct violation of the prescribed rules for mixing, and even then it rapidly disappears by conversion into more complex compounds of good fertilizer value.

The Paint and Varnish Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—I wish to call your attention to an article by Dr. Maximilian Toch in CHEMICAL & METALLURGICAL ENGINEERING, vol. 23, No. 10, Sept. 8, 1920, pp. 469 and 470, entitled "Putting the Paint and Varnish Industry on a Scientific Basis." The statements therein made are so at variance with the facts that it is unfair to the paint and varnish industry and to chemists long engaged in this industry to allow them to remain uncorrected.

Early in the article he states: "Prior to 1906 the most impossible and worthless mixtures paraded under the name of paint." This was doubtless as true then as it is today. He fails to state the noteworthy fact that in 1906 a considerable number of thoroughly reliable, well-equipped paint manufacturing concerns were and for many years prior thereto had been turning out large quantities of paint of a quality which has never been surpassed.

His statement, "There was at that time no literature on the subject," is entirely erroneous. He names five men who "were the only chemists in the United States who had at that time any knowledge of the chemistry of paints." In addition to these, he states, "There were perhaps three or four more like" (two names mentioned) "and others who did private work."

As a matter of fact, Dr. Toch in 1906 was listed in the membership of the American Society for Testing Materials as a paint manufacturer, and in the membership of the Society of Chemical Industry as a chemist. Within these two societies in 1906 there was a goodly number of men who had knowledge of paint chemistry.

At least twelve varnish companies were represented in the membership of the American Society for Testing Materials or the Society of Chemical Industry, or both, and of these twelve at least eight employed chemists. Other companies not so represented employed chemists. At least eighteen paint companies were represented by membership in these societies, either directly or indirectly, and of these eighteen at least ten employed chemists. Other companies not so represented employed chemists. At least fifteen great railway systems were represented by membership in these societies and all of these employed chemists, many of them engaged in work similar to that of Dr. C. B. Dudley.

The membership list also discloses (in addition to the two mentioned by Dr. Toch) at least five in New York City, one in Boston, one in Baltimore, one in Philadelphia, one in Pittsburgh and one in Chicago, engaged in private work. The membership list discloses at least one expert in paint and varnish chemistry in the federal service.

The following list is certainly not a complete roster of all the chemists who in 1906 had "any knowledge of the chemistry of paints." It is a partial list of those found in the societies mentioned, and also includes a few holding official position who may not have been

chemists. Membership in the American Society for Testing Materials is indicated by (a) and in the Society of Chemical Industry by (b):

- (a) Alcott, F. L., engineer of tests, Chicago, Milwaukee & St. Paul Ry.
- (b) Andrews, W. H., manager varnish works.
- (a) (b) Austen, Peter T., consulting chemist.
- (a) (b) Bailey, R. W., chemist, Stillwell & Gladding.
- (a) (b) Baringer, F. J., chemist, Eagle White Lead Works.
- (a) (b) Bjerregaard, A. P., varnish chemist, Emil Calman Co.
- (a) Blanch, J. C., superintendent Blanchite Process Paint Co.
- (a) (b) Browne, Arthur I., consulting and analytical chemist.
- (a) Bunnell, F. O., engineer of tests, Chicago, Rock Island & Pacific Ry.
- (a) (b) Burleigh, William F., technical chemist, Murphy Varnish Co.
- (a) (b) Cheeseman, Frank P., paint manufacturer.
- (b) Clark, Homer, chemical manufacturer, Vacuum Varnish & Chemical Co.
- (a) Dabbs, Harold M., L. J. McCloskey & Co.
- (a) Davidson, George M., engineer of tests, Chicago & Northwestern R.R.
- (b) Dreyfus, L. A., chemist, the Mural Co.
- (a) (b) Dudley, C. B., chemist, Pennsylvania R.R.
- (a) (b) Edgerly, D. W., chemist, Chilton Paint Co.
- (a) (b) Forrest, C. N., chemist, New York Testing Laboratory.
- (a) (b) Frank, Jerome W., chemist, Standard Varnish Works.
- (a) Gibboncy, James H., chief chemist, Norfolk & Western Ry.
- (a) (b) Gill, A. H., assistant professor of technical analysis, Massachusetts Institute of Technology.
- (b) Gladding, T. S., chemist.
- (a) (b) Handy, J. O., chemist, Pittsburgh Testing Laboratory.
- (a) (b) Harriman, N. F., chemist and engineer of tests, Union Pacific Ry.
- (a) (b) Holton, E. C., chemist, Sherwin-Williams Co.
- (a) (b) Hooker, A. H., chief chemist, Heath & Milligan Co.
- (a) Hunt, Robert W., Co. Laboratory.
- (a) Ingalls, F. P., chemist, John W. Masury & Sons.
- (a) (b) Job, Robert, chemist, Booth, Garrett & Blair.
- (a) (b) Kittredge, H. G., chemist, Kay & Ess Co.
- (a) Kohr, D. A., chemist, Lowe Bros.
- (a) Knapp, A. C., manager, railway department, Parrott Varnish Co.
- (a) (b) Little, Arthur D., consulting chemist.
- (a) Lord, Richard C., engineer of tests, Louisville & Nashville R.R.
- (a) (b) Lowe, Huston, paint and varnish maker.
- (a) Lucas & Co.
- (a) McFarland, J. A., chemist, Missouri Pacific Ry.
- (a) (b) McIlhiney, Parker C., chemist.
- (a) (b) McKenna, Charles F., chemist.
- (a) (b) Mahon, R. W., chemist, New York Central & Hudson River R.R.
- (b) Mannhardt, Hans, chemist, Heath & Milligan Co.
- (a) Marshall, William, president, Anglo-American Varnish Co.
- (a) Minwax Coatings Co.
- (a) Patterson Sargent Co.
- (a) Patton, Ludington, secretary-treasurer Patton Paint Co.
- (b) Perry, R. S., president, Harrison Bros. & Co.
- (a) Phlegar, A. A., Jr., chemist, Norfolk & Western R.R.
- (a) Picher Lead Co.
- (a) Powers, W. A., chief chemist, Atchison, Topeka & Santa Fe R.R.
- (a) Riddle, Walter V., president Sterling Varnish Co.
- (a) (b) Sabin, A. H., chemist, varnish works.
- (a) Scott, W. G., chemist, J. I. Case Co.
- (a) (b) Smith, H. E., chemist, Lake Shore & Michigan Southern Ry.
- (b) Stillwell, A. G., chemist.
- (a) Suydam, Richard S., president, M. B. Suydam Paint Co.

- (a) (b) Thompson, G. W., chemist, National Lead Co.
- (a) (b) Toch, Maximilian, paint manufacturer, chemist.
- (a) (b) Van Gundy, C. P., chief chemist, Baltimore & Ohio R.R.
- (a) Von Marle, C. M., chemist, Pratt & Lambert.
- (a) (b) Voorhees, S. S., engineer of tests, Treasury Department, Washington, D. C.
- (b) Worstall, Robert A., chemist, Chicago Varnish Co.
- (a) Wickhorst, Max H., engineer of tests, Chicago, Burlington & Quincy Ry.
- (a) Wilhelm Co., The.
- (a) Woods, R. W., chief chemist, Northern Pacific Ry.

Of the thirty-eight listed as members of the Society of Chemical Industry in 1906 thirteen had been in the society for ten or more years.

E. C. HOLTON.

Cleveland, Ohio.

To the Editor of Chemical & Metallurgical Engineering

SIR:—With reference to Dr. Holton's letter, let me say that when I mentioned that there were only three or four more chemists in 1906 who did real work on the chemistry of paint, I should have mentioned him because undoubtedly he was one of the pioneers and entitled to a niche in the hall of fame in the chemistry of paints. His list marked "a" and "b" of members of the American Society for Testing Materials and members of the Society of Chemical Industry means very little, however, for in looking over these lists I notice the names of some who are no longer living; also many who know nothing about the chemistry of paints today. A man may be an excellent chemist in general chemistry and yet know nothing about the chemistry of our particular line. I hope Dr. Holton will realize that no discourtesy was intended by omitting his name; but I am unable to agree with his imposing list which, while it contains the names of many good chemists, lists only a few who have within the past fourteen years come sufficiently to the front to be classed as paint chemists.

New York City.

MAXIMILIAN TOCH.

Important Leather Factory in Alsace Changes Hands

The announcement is made in the French press that the German firm of Adler & Oppenheimer, located at Lingolsheim, a suburb of Strasburg, and considered the largest leather factory in Europe, has been sold to a group of French and Alsatian interests for 32,000,000 fr. The group includes important financiers and business men. The new organization is constituted under the name of Les Tanneries de France, with a capital of 50,000,000 fr. divided into 500,000 shares of 100 fr. each. The plant is capable of realizing an annual turnover of from 200,000,000 to 250,000,000 fr. It is intimated that special attention will be given to exporting the products of the factory. When the Adler & Oppenheimer plant was placed under sequestration by the French considerable fear existed among French tanneries regarding the possibility of serious competition from the newly acquired factory. It is very well situated for the purpose of export to foreign countries.

Porous Plates Hard to Get

Numerous complaints having reached the chief chemist of the Bureau of Mines as to the difficulty of securing porous plates for laboratory use, the bureau is inquiring into the situation in the hope that it may be helpful in making possible a more adequate supply of these utensils.

Gas Analysis by Absorption and Titration

The Method of Gas Analysis by Absorption and Titration Has Been Simplified by the Use of a Gas Volume Compensometer for Measuring the Volume of Residual Gas, and an Alignment Chart for Calculating the Results

By R. S. TOUR

FOR more accurate determination of certain constituents in gases—e.g., NH_3 , CO_2 , SO_2 , H_2S —it is best to absorb the constituent in a suitable reagent, the volume of residual gas being measured, and the absorbing solution titrated. The accuracy then is that of the standard solutions, of the titration or of the measurement of the gas. Assuming the standardization and titration within the limits of accuracy desired, it becomes necessary to measure the volume of gas with the same accuracy and correct it to some known standard condition e.g., 760 mm., 0 deg. C., dry. There then remains merely the calculation of the content of the absorbed constituent in the original gas.

The measurement of the gas and its volume correction may be greatly simplified by the use of a "compensometer," while the final calculation may be accomplished graphically with the aid of a nomograph.

GAS VOLUME COMPENSOMETER

The gas volume compensometer here described may be used to measure gas at room temperatures and pressures and to give at the same time a factor for converting this volume to standard conditions (760 mm., 0 deg. C., dry) or to read directly the corrected standard volume. The apparatus as shown in Fig. 1 is designed for an accuracy of ± 0.5 per cent, although with some modifications an apparatus of much greater accuracy could be obtained.

Manipulation of the apparatus is simple. The gas to be measured is drawn through the double inlet stopcock and displaces the water in the gas flask. This can be accomplished by lowering the leveling bottle connected to the water exit of the flask, or more simply by using slight pressure on the gas to raise the water into the bottle. The gas flask is marked for some definite or convenient volumetric displacement. When water has been discharged to this point, the water exit is closed by the stopcock in that line or by pinching the rubber tube and the double inlet gas stopcock is turned to communicate with the manometer. The scale on the manometer reads either the correction factor or the corrected volume (at 760 mm., 0 deg. C., dry) of the gas within the flask.

The apparatus consists essentially of a measuring gas flask completely inclosing a compensator which connects to one leg of a manometer, the other leg of which can be opened to the gas within the measuring flask. The compensator pressure on one leg of the manometer indicates the temperature correction and if a drop of water has been inclosed within the compensator the correction includes that for water vapor pressure. The pressure of the gas in the flask acting on the other leg of the manometer tends to balance

the compensator pressure and the manometer actually indicates the net correction to be applied.

Let P, p = total pressures in mm. Hg.

" T, t = temperature in deg. C. abs.

" V, v = volumes in c.c.

" A, a = water vapor pressures.

Let capitals above represent gas flask conditions and let small letters represent compensator conditions.

Let B = barometric pressure in mm. Hg.

" D = gas flask displacement in c.c.

" m = compensator manometer pressure in mm. Hg.

" K = compensator constant.

" C = conversion factor to standard conditions.

Let subscript s be used for standard conditions.

Let subscript r be used for compensator conditions at time of scaling.

Let subscript c be used for calibrating conditions.

Let subscript x be used for any operating condition.

The manometer is sealed with mercury under such

FIG. 1. GAS VOLUME COMPENSOMETER

compensator conditions as to give approximately no pressure differential at the average operating conditions of the apparatus. All pressure readings (m) on the manometer are to be measured from a true zero pressure point which includes a correction for capillarity.

FIG. 2. NOMOGRAPH FOR CALCULATING RESULTS OF GAS ANALYSIS BY ABSORPTION AND TITRATION

For calibrating the apparatus it is necessary to determine the compensator constant (K) which is based on the conditions (p_r , t_r , a_r) at which the compensator was sealed. To do this, place water of known temperature within the flask about the compensator, leaving the flask leg of the manometer open to the atmosphere. For our purposes, the compensator volume is constant and independent of the manometer reading if the manometer tube be capillary.

$$\text{Then } \frac{p_r}{t_r} \cdot \frac{a_r}{t_r} = \frac{p_c}{t_c} \cdot \frac{a_c}{t_c} = \frac{B_c + m_c}{t_c} \cdot \frac{a_c}{t_c}$$

The temperature of calibrating determines t_r , as well as a_r , which may be read from vapor pressure tables, and p_r is equal to the barometric pressure (B_c) plus any small manometer pressure (m_c). The value of the term $\frac{p_r}{t_r} \cdot \frac{a_r}{t_r}$ is thus determined and may be known as the compensator constant (K).

For graduating the manometric scale to read in terms of the conversion factor (C) to standard conditions (760 mm., 0 deg. C., dry), note that

$$T_x = t_x, A_x = a_x, P_x = p_x = m_x, \frac{p_x}{t_x} \cdot \frac{a_x}{t_x} = K$$

Hence

$$C_x = \frac{V_x}{V_r} \cdot \frac{T_r}{P_r} \cdot \frac{A_r}{A_x} \times \frac{P_x}{T_x} \cdot \frac{A_x}{T_x} = \frac{273}{760} \cdot \frac{4.6}{4.6} \times \frac{p_x}{t_x} \cdot \frac{a_x}{t_x} \cdot m_x$$

$$\text{or } C_x = 0.361 \left[K \cdot \frac{m_x}{t_x} \right]$$

The term $\frac{m_x}{t_x}$ is the correction term for the variation from the average operating conditions represented in K .

In ordinary practice the value of $\frac{m_x}{t_x}$ at its maximum will be under 10 per cent of K and the value of t_r is subject to a maximum variation of ± 5 per cent. Hence the average value of t_r can be assumed.

If the average value of t_r be taken at 298, or 25 deg. C., then $C_r = (0.361K) = \frac{m_r}{825}$. This represents a variation of 0.010 in the numerical value of C for each 8.25 mm. pressure on the manometric scale. The scale can then be graduated to read C directly, and for ordinary operation the range 0.800 to 1.000 covering 165 mm. is ample. If the average value of t_r be 289 (16 deg. C.), then each 8 mm. of the scale represents a variation of 0.010 in the value of C . If it is desired that the reading be directly in corrected volume, the scale is graduated according to $C_r D$. It is suggested that one point of the scale (e.g., $C = 0.90$) be permanently etched on the manometer tube.

CALCULATIONS

Having obtained the necessary data, there remains the calculation for the percentage content of the constituent to be determined in the original gas.

Let Q = c.c. of reagent used for titration.

" N = normality of reagent.

" R = c.c. of 0.10 normal reagent used.

" V = c.c. volume of residual gas corrected to standard conditions.

" J = valence of absorbed constituent.

" Y = per cent of absorbed constituent in original gas.

Then $22.4 \frac{NQ}{J}$ c.c. of constituent absorbed.

$$\text{And } V + \left(22.4 \frac{NQ}{J} \right) = \frac{100}{Y} \left(22.4 \frac{NQ}{J} \right)$$

$$\text{Or } \frac{100}{Y} \cdot \frac{Y}{J} = \frac{VJ}{22.4NQ}$$

Taking J at unity and the normality of the standard solution at 0.100 (which solution is in general very satisfactory) then $\frac{10NQ}{J} = R$

CONSTITUTION OF NOMOGRAPH

A nomograph for the graphical solution of the above equation is shown in Fig. 2. It has been of great help in routine laboratory analyses. For use a rule is laid across the three scales so that it cuts the R scale at the number of c.c. of 0.10 N reagent used and cuts the V scale at the number of c.c. residual gas measured in the compensometer. The intersection of the rule on the Y scale then reads directly the per cent of absorbed constituent in the original gas.

For plotting the nomograph with the same proportional accuracy throughout its scale, the logarithmic form of the equation was used:

$$\log \frac{100}{Y} \cdot \frac{Y}{J} = \log V = \log R = \text{constant}$$

The nomograph shown has an accuracy greater than ± 0.5 per cent with scales and ranges as follows:

	R Scale 10 NQ J	V Scale $C_r D$ C.c. Residual Vol. 760 Mm. 0 Deg. C. Dry	Y Scale Per Cent Composition by Volume
I. Range	0.6 to 6.0	600 to 1,200	0.1 to 2.0
II. Range	6 to 60	600 to 1,200	1 to 20

In this case $\frac{10NQ}{J}$ has been taken equal to R . If any

other conditions than $J = 1.0$ and $N = 0.10$ apply for using the nomograph, the actual titration value Q as obtained can be corrected. For special absorption determinations where V may be very large, R may be proportioned so as to reduce V within the nomograph range.

For the determination of NH_3 in gas mixtures, for which particular analysis the compensometer and nomograph have been devised, the compensometer draws 800 to 1,000 c.c. of gas and reads the corrected volume directly on the manometer scale, the value of J is 1.0, 0.10 N acid is very satisfactory, and the nomograph reads directly the per cent volume of absorbed constituent.

Apothesin as a Local Anæsthetic

A pharmaceutical compound about which little has appeared in the literature and which has earned a place among the prominent local anæsthetics bodies because of its merits is apothesisin. The cinnamic ester of gamma-diethylamino propyl alcohol is made as follows: Thirteen parts, by weight, of gamma-diethylamino propyl alcohol are dissolved in eighty parts, by weight, of benzene, and to this solution sixteen parts, by weight, of cinnamoyl chloride are gradually added. The solution deposits the hydrochloride of gamma-diethylamino propyl cinnamate in the form of white crystals, readily soluble in water, and having a melting point of 137 deg. C. This body is recrystallized from a mixture of alcohol and ether and is then ready for use. The alcohol is prepared from trimethylene glycol, a byproduct in the manufacture of soap.

Some Notes on the Effect of Nitrogen on Steel

Work Showing at Least Five Definite Layers Are Produced on the Surface of Low-Carbon Steel When It Is Exposed to Ammonia at 650 Deg. C.—Excessive Brittleness in the Outer Zones Responsible in Part for Gun Erosion

BY O. A. KNIGHT AND H. B. NORTHRUP*

IT HAS long been known that nascent nitrogen formed by the decomposition of ammonia at elevated temperatures has a deleterious effect upon a number of metals and alloys. In this connection a number of papers have been published covering the pioneer work on the subject, as well as some later ones covering the progress of further research. A few of the more important references are given below.¹

The need of further investigation of this subject was brought to the attention of each of the authors of this paper, working severally as metallographist at the Watertown Arsenal, Watertown, Mass., and metallurgist for the Engineering Division, Ordnance Department, attached to the Bridgeport District Ordnance Office.

EXPERIMENTAL EQUIPMENT

The present investigation was carried out in order to determine the effect of ammonia on the microstructure and physical properties of steel and its possible relation to the erosion of guns, corrosion, deterioration of nitrating cylinders, etc. The effect of ammonia on a number of other alloys was also studied in an attempt to find a metal or an alloy which would not appreciably deteriorate under the influence of ammonia at elevated temperatures, and this paper consists of notes of observation which the writers have recently made and which they believe will be of value to add to the already existing data. It is with this object in mind that these notes are published.

Owing to the fact that the deterioration noticed by the writers was always accompanied by marked changes of microstructure it was believed that a study of the effect of ammonia on the microstructure would give direct evidence of its effect on the physical properties. Therefore the preliminary work consisted of a search for a metal or alloy whose structure would not be materially affected by ammonia at elevated temperatures.

In view of the fact that the deleterious effects above mentioned took place at a low red heat, and also that several industrial processes (the Haber process for producing ammonia, and others) involve the use of ammonia near this temperature, it was decided that the present experiments be conducted at a temperature of 650 deg. C.

The specimens in question were treated in a furnace of the electric resistance type. The resistor was wound upon an alundum core through which was inserted a glazed silica tube 1½ in. in diameter, inside of which the specimens were placed for the nitrogenizing treat-

ment. Ammonia gas was generated by heating c.p. aqua ammonia in a flask, the gas being passed through a condenser, over lime, and thence through the silica tube. The temperature was accurately controlled by the use of a platinum thermocouple checked against a couple of the same type carrying a Bureau of Standards certificate. The emf. generated was measured by a Leeds & Northrup portable potentiometer.

This work has consisted in the investigation of many grades of iron, steel and other alloys, having been under way for approximately two years. Since this work was begun an article by H. E. Wheeler, entitled "Nitrogen in Steel in the Erosion of Guns," has appeared in Bulletin 160, of the A.I.M.E.,² in which article a great many of the metals investigated by the present writers and several others are described with reference to the effect of nitrogen on them under similar conditions. Therefore, since the appearance of this paper, the contents of which in many instances check the results of the present experiment, the major portion of the writers' work will not be reproduced. In phases of the work where the results of Wheeler do not check the observations of the writers discussion will follow later on.

An early part of the investigation consisted in heating ¼-in. (3-mm.) diameter steel wire tensile specimens in an atmosphere of ammonia at 650 deg. C. for varying lengths of time at a pressure of about 840 mm. mercury, and the subsequent heating of some of these specimens in hydrogen. Tensile tests and microscopic examination were carried out. Pressure of about 840 mm. of mercury was maintained on the ammonia gas, as previously mentioned, by means of an open-arm manometer.

HEATING IN AMMONIA AND HYDROGEN

Nine specimens of annealed steel wire ¼ in. in diameter, 10 in. in length (3 x 254 mm.) and containing C 0.81 per cent, Mn 0.56, Si 0.17, S and P less than 0.04 were selected for treatment. Three were pulled in the annealed, untreated condition. The six others were treated in ammonia gas for eight hours at 650 deg. C. and furnace-cooled in ammonia gas. Three of these were tested in the tensile machine, and the other three were heated in hydrogen for eight hours at 650 deg. C. and furnace-cooled. They were then tested in the tensile-testing machine. Hydrogen was generated by the action of sulphuric acid on pure zinc; it was dried before passing through the furnace by bubbling through pure sulphuric acid.

The average results of these tests are given in Table I.³

As will be seen from this table, the effect of heating in ammonia diminished the tensile strength and greatly reduced the elongation, while the reduction of area was rendered zero. This low value of the tensile strength

³Taken from thesis work of E. K. Mull and W. I. Pottelger, 1919.

can easily be accounted for by the extreme brittleness of the outside hard surface, which developed circular cracks extending completely around the specimen upon the application of a few thousand pounds per square inch. This cracking effect not only decreases the area of cross-section remaining but opens up a path of fracture which will continue through the interior, though

TABLE I.

Condition of Steel	Tensile Strength—		Elongation in 2 In., per Cent	Reduction of Area, per Cent
	Lb. per Sq. In.	Kg. per Sq. Mm.		
Annealed, not treated	98,500	69.2	13.6	22.1
Annealed, heated in NH_3 for 8 hr at 650° C.	79,500	55.9	2.0	0.0
Annealed, heated 8 hr in NH_3 at 650° C., followed by heating 8 hr in H at 650° C.	89,000	62%	4.5	6.6

no doubt more ductile, portion. It will be noticed that heating in hydrogen partly restored the normal physical properties, and no doubt prolonged heating in this manner would completely restore the original physical properties. Microscopic examination showed the irregular *white layer* (so frequently discussed by other investigators and mentioned later) to be all removed by hydrogen treatment and the structure back of it partly restored to normal. Heating in hydrogen did not remove the effects of the ammonia treatment as fast as they were induced.

SEARCH FOR METAL UNAFFECTED BY AMMONIA

A series of experiments were next carried out with the object of finding, if possible, a metal which would stand up under the action of NH_3 at elevated temperatures. In this series no physical tests were attempted; microscopic examination alone was relied upon as a means of testing, since it has been found that the deterioration is accompanied by very distinct changes in microstructure. Therefore the object was to find a metal whose structure would be little (if any) affected by ammonia gas at 650 deg. C. and under a pressure slightly greater than atmospheric. The results of these tests may be briefly summed up as follows:

Pure tungsten does not seem to be affected by the ammonia treatment. All other pure metals tested were affected. Wrought iron and low-carbon steels are readily attacked. High-carbon steels are much more resistant than wrought iron and low-carbon steel. White cast iron is affected on the surface, but not deeply. Chromium-vanadium steels are in general the best class for resisting this action so far studied by the writers. Stellite is practically unaffected, and the alloy nichrome is also little affected; monel metal is slightly attacked.

Those metals which were only slightly attacked are either impractical to apply as containers for NH_3 at elevated temperatures and pressures on account of their price or on account of undesirable physical properties, such as brittleness, hardness too great to permit machining, etc. Therefore this series of experiments seems to be of value only in a negative way.

EFFECT OF AMMONIA ON CARBON STEELS

It was then decided to study carefully the effect of ammonia on all the different grades of plain carbon steel, keeping all elements constant except the carbon and varying it from practically pure iron to hypereutectoid steels. This was carried out as follows: A piece of 0.07 per cent C steel, other elements normal, $\frac{1}{2} \times \frac{1}{2} \times 1$ in. (13 x 13 x 26 mm.) was casehardened by heating to and holding at a temperature of 950 deg. C.

in a packing of Rodman Chemical Co.'s "Carbo S" case-hardening compound for three hours and furnace-cooled. After this the specimen was removed and cut in two in the central part of its longest dimension, the surface cut being normal to the greatest axis. The surface thus exposed on the freshly-cut face varied in carbon from 0.07 per cent near the central portion to about 1 per cent on the outside (hypereutectoid distinctly), with the other elements remaining constant, unless a change took place in the percentage due to impurities in the carbonizing material.

Careful microscopic examination was made of one half of the casehardened specimen; the other was ground to a smooth surface and heated to 650 deg. C. in ammonia for twelve hours and furnace-cooled. After this treatment the specimen was removed from the furnace and cut in two on a plane normal to the surface previously exposed by cutting in two the first time. This then presented for study a surface whose carbon content ranged from 0.07 to about 1 per cent, increasing gradually, and which had been exposed alike to the action of ammonia at 650 deg. C. The specimen was then carefully mounted, as usual, in a low fusing point ductile alloy, the melting point of which was about 95 deg. C., after which it was polished for micro-examination.

Nothing unusual was noticed in the unetched condition, so the specimen was etched five seconds in 4 per cent nitric acid in absolute alcohol. It was examined along the entire edge from high-carbon to low. A very uniform layer was found all along and its average depth was 0.0073 in. (0.19 mm.), with only very slight variations from that figure. The nature of this layer was the same in the high-carbon area as in the low. The accompanying photomicrographs are arranged with the edge, or extreme outside of the steel, up and the interior portion down i.e., below it on the page. Lines have been drawn to make clear the location of the areas under discussion. Fig. 1 shows this layer between the lines A-A and B-B taken on the low-carbon area. The structure above the line A-A, out of focus, is that of the alloy used for mounting, and which holds the hard brittle layer firmly in place. This layer, between lines A-A and B-B, etches differently on the outside three-fifths (approximately) than on the inner two-fifths. The outer portion is darkened and a sort of granular or finely pitted effect is revealed, while the inner two-fifths is unaffected or only slightly so by five seconds' etching. The discussion of the structure which lies deeper in—i.e., below line B-B—will be left till later on, but it is now desired to confine attention to this outside layer. Fig. 2 between the lines A-A and B-B shows this same layer in the region of highest carbon content. It (the normal steel) is hypereutectoid, as seen by the excess cementite around the large grains in the lower left of the picture. The thickness of this outside layer, or "case" as it will be termed in this paper, is practically the same for all the different carbon concentrations and its nature seems likewise the same. The high-carbon portion seems to etch a trifle faster, if any. Longer etching has the effect of simply intensifying the corrosive action on the outer three-fifths of the layer, making it darker, as etching progresses, until black. An entirely different effect is observed on the inner two-fifths of the case, which remains comparatively bright and structureless after etching five seconds in 4 per cent nitric acid in alcohol. Longer etching develops an interesting structure in this area. There is a definite crystalline structure and

FIGS. 1 TO 3. STRUCTURE OF NITROGENIZED LAYER ON CEMENTED STEEL. 125 DIA. HNO₃ ETCHING.
 Fig. 1. Low carbon region. Fig. 2. High-carbon region. Fig. 3. Layer after long etching.

the crystals are of a columnar nature with their major axis normal to the outside surface. This is shown in Fig. 3 at 125 diameters after etching with 4 per cent HNO₃ for twenty-five seconds. Between the dark outside and the light columnar crystalline structure will also be seen several fine lines, having the appearance of cracks.

Further study of this portion of the case containing the columnar crystals was made at higher magnification and after longer etching.

STRUCTURE OF CASE PRODUCED BY AMMONIA

The photomicrograph shown in Fig. 4 shows the structure of the area containing the columnar crystals as revealed by etching thirty-six seconds in 4 per cent nitric acid in alcohol and at a magnification of 400 diameters. The columnar crystals are shown distinctly as well as the fine hair cracks previously mentioned. Each one of these columnar crystals has striations crossing it in some direction and all the striations are parallel in the same crystal but extend in different directions in different crystals. The base of these crystals forms practically a straight line, and a sharp line of demarcation separates this structure from the pearlitic structure just beneath it.

The hardness of the outside layer or case is greater than any other portion. This was determined by drawing a needle point over the surface at a uniform pressure. A deep impression (microscopically) was cut in the metal by the needle point up to the case, but there very little effect was produced. The specimen was scratched after etching and the marks could be seen under the microscope to be very slight on the outside layer in comparison to the effect on the metal back of it. Rubbing the specimen gently on the rouge pad removed all traces of the scratches on the case but left deep markings on the rest of the metal. The case was much harder than the high-carbon portion of the steel, and so far as could be determined by this simple method of testing its hardness is more clearly equal that of cementite than any other constituent.

Before leaving the discussion of this outside "case"—i.e., the layer extending from the extreme outside to the base of the columnar crystals—the writers wish to emphasize more strongly its extreme brittleness. Attention is again invited to the cracks shown so vividly in the photomicrograph reproduced in Fig. 4 somewhat above and parallel to the base of the columnar crystals. The specimen was taken out of the fusible alloy and in

order first to determine if these cracks were a result of sudden heating when the specimen was mounted in this alloy the specimen was heated very quickly on the edge by plunging in a bunsen flame. Examination after this treatment showed no further development of cracks. After this the edge was gently struck with the edge of a spatula at different places and again examined microscopically. The extreme outside of the case was found to have fractured along the hair cracks shown in the photomicrograph reproduced in Fig. 4. This occurred at every place the specimen was struck, and the line of fracture was always the same—i.e., near the tops (exterior ends) of the columnar crystals, consequently within the light portion of the case.

NECESSITY OF MOUNTING BEFORE POLISHING

It was noticed that in all specimens not mounted a distinct but irregular white layer was present. This was because the exterior portion, which etches dark, has been lost during the polishing operation due to its extreme brittleness. Losses of this sort occurred after polishing early in the present investigation, until it was observed that a very constant increase in weight was obtained by giving like gas annealing to like specimens.

FIG. 4. COLUMNAR CRYSTALS IN NITROGENIZED LAYER. ETCHED 36 SEC. IN 4 PER CENT ALCOHOLIC NITRIC ACID. $\times 400$

With the possibility that spalling could be giving the erratic microscopic results, mounting was resorted to. When this was done examination showed very regular depths of case when like specimens were treated in the same way. This is somewhat contrary to Wheeler's views, which he expresses on page 30 of his paper (*Mining and Metallurgy*, No. 160, April, 1920) as follows:

"The object of treating a number of alloy steels twenty hours in NH_3 at 650 deg. C. and in some cases at 750 deg. C. was to observe the depth of the case formed and gather an idea of the effect of the added element in retarding or accelerating this reaction. The method is far from quantitative. For instance, two steels, each of 0.40 per cent carbon and 1 per cent chromium, one of 0.20 per cent vanadium and the other of 0.25 per cent vanadium, would not give in half a dozen experiments consistent results as regards the depth of penetration. Such fine distinctions are beyond the scope of this method."

While Mr. Wheeler does not mention whether or not his specimens were mounted before polishing, nor does he mention the extreme brittleness of the outer surface exposed to NH_3 , the present writers fear, in case his specimens were not mounted, the spalling of the edge led him to conclusions which are not quite correct.

Let us examine a few photomicrographs, in this connection, prepared by the writers of specimens mounted and not mounted. The photomicrograph shown in Fig. 5 shows the type of case produced by treating a plain low-carbon steel in NH_3 twelve hours, followed by furnace-cooling and polishing with great care in the ordinary way—i.e., not mounted. The case is seen to be very irregular. Other views at the same magnification and nearly the same location on the same specimen give white cases from one-third to one-fifth the thickness. Another steel of eutectoid composition showed such irregular and jagged edges as are revealed in Fig. 6.

As soon as such gross irregularities as this appeared as a result of microscopic examination and in view of what would be expected from the gain in weight observed on many treated specimens it was decided at once that mounting was necessary to make an accurate study of this case.

Table II gives the weight before and after treatment in NH_3 , together with the actual and percentage increase in weight, of six specimens of steel wire $\frac{1}{8}$ in. in diameter and cut approximately to the same length.

One can see at a glance that a greater degree of regularity exists in weight gain than would be expected from such an irregular surface. Consequently the specimens from this time on were mounted in the low melting point alloy previously mentioned. This resulted in uniform cases, as was expected. The photomicrograph

TABLE II. GAIN IN WEIGHT OF $\frac{1}{8}$ -IN. WIRE AFTER AMMONIA ANNEALING

specimen No.	Weight Before NH_3 Treatment	Weight After NH_3 Treatment	Gain in Weight	Per Cent Gain
1	3.5822	3.6104	0.0282	0.79
2	3.9745	4.0045	0.0300	0.75
3	4.1864	4.2166	0.0302	0.72
4	4.3250	4.3550	0.0300	0.70
5	3.9836	4.0128	0.0292	0.73
6	3.9621	3.9909	0.0288	0.73

reproduced in Fig. 8 shows the same steel as shown in Fig. 5 (at 125 diameters instead of 200, because all the case could not be conveniently shown at high power).

This degree of uniformity was found on all specimens mounted, though in some instances the case would be cracked, but held in place by the low melting point alloy.

Inspection of all of Mr. Wheeler's photomicrographs shown in his excellent paper noted above, taken on the edge of specimens to show the depth of case, shows that none were mounted. On account of this the present writers are very skeptical regarding the accuracy of some of the conclusions to which he has been led.

PEARLITIC LAYER UNDER BRITTLE SURFACE

Let us turn now to the rest of the microstructure produced by the ammonia treatment. Referring again to Fig. 1, taken in the region of low-carbon content, a thin dark layer, appearing to be high in carbon, is seen at the inside of and immediately next to the white layer—that is, at the base of the columnar crystals. Examination of this layer at higher magnification reveals a pearlitic structure, as shown clearly in Fig. 4, at 400 diameters. This layer was scrutinized microscopically from the low- to the high-carbon region, and it had the same appearance all along. In the high-carbon area it was in the form of pearlite grains, each grain surrounded by a thin film of excess cementite, seemingly the same as the normal structure, so that nitrogenization in this region produced the so-called "case" previously described, beneath which there was no evidence of a change in microstructure.

FIGS 5 TO 7. VARIATION IN SURFACE LAYERS CAUSED BY POLISHING METHODS, HNO_3 ETCHING

Fig. 5. Low-carbon steel, polished without mounting. $\times 200$.

Fig. 6. Eutectoid steel, polished without mounting. $\times 200$.

Fig. 7. Same steel as Fig. 5, polished after mounting. $\times 125$.

FIG. 8. SO-CALLED NITROGEN NEEDLES BENEATH THE SURFACE. $\times 125$. HNO_3 ETCHING

In the low-carbon region something entirely different is observed. First, a thin layer (approximately 0.0007 in. or 0.017 mm. in thickness) pearlitic in appearance is found just beneath the columnar crystals; then comes a layer whose thickness equals about the width of two rows of ferrite grains, in which the structure of these two rows of ferrite grains appears normal. Just beneath this is found a layer of considerable thickness (not measured, but of greater thickness than all the other layers combined), in which the ferrite grains are found to contain a great number of the (so called by other investigators) nitrogen needles. This is shown in Fig. 8, at 125 diameters. Below this the normal structure of the low-carbon steel prevailed.

Restating conditions, we may say that in the high-carbon region there is a very brittle "case," which on its outer three-fifths etches dark and on its inner two-fifths light at first but depicts columnar crystals on further etching, beneath which case no change of structure was observed, whereas in the low-carbon area the same type and depth of "case" was observed, beneath which was a thin layer pearlitic in structure or pearlitic containing some sorbite, beneath which in turn was a layer about two grains in width which appeared unaffected; then follows the area containing nitrogen needles, and then the true normal structure. It is clear from this that in so far as microscopic examination of a sample etched with HNO_3 is able to show the nitrogen liberated by decomposing ammonia under the conditions stated has a far greater penetrating power on low-carbon than on high-carbon steel. It is recognized that nitrogen needles may be effectively masked by pearlite normally existing in high-carbon steels.

An explanation as to the reasons for the formation and existence of the different types of structure here shown will be left until more data are accumulated.

Specimens were etched with Stead's reagent, iodine, and boiling sodium picrate. Stead's reagent blackened the outside three-fifths of the case very quickly with a heavy copper deposit, while the nitrogen needles were light in a dark background. The columnar crystallization was vividly shown and the thin layer immediately

beneath it was darkened. Boiling sodium picrate developed a most interesting structure, but the writers wish to withhold a discussion of these results until further study can be made, when a slightly higher melting point alloy will be used for mounting the specimens so they will not become loosened during the etching. Iodine gave no results that were not better shown by some other reagent.

CORROSION AND CASEHARDENING

A series of experiments were carried out to determine if the case produced by ammonia was of any value in resisting corrosion. Several specimens of 0.80 carbon steel were subjected to the action of ammonia at 650 deg. C. for twelve hours, after which they were given accelerated corrosion tests. As compared to the same steel not treated in ammonia the specimens thus treated were much more resistant to corrosion provided the specimen, after nitrogenization, was not subjected to stresses which would develop cracks in the brittle case. Specimens were tested which had the case intentionally cracked by light stresses, and these gave very poor corrosion tests. Since the case fractures so easily it is hardly possible that it can be useful in this way. As to casehardening, the writers firmly believe that cyanogen compounds used for casehardening give more brittle cases than compounds which do not contain cyanogen and that this brittleness is due to nitrogen. This was suggested earlier by Le Chatelier, and Braune reports needles similar to "nitrogen needles" in *Revue de Metallurgie*, 1905, vol. 2, p. 497, in his report on baths containing cyanide and ferrocyanide of potassium.

NITROGEN (OR CHEMICAL) THEORY OF THE EROSION OF GUNS

Early in 1917, when the first of the present writers was studying the erosion of two 10-in. rifles at the Watertown Arsenal, Watertown, Mass., a report of which will be found on page 245 of "Tests of Metals and Other Materials at the Watertown Arsenal During the Fiscal Year Ended June 30, 1917," he was led to believe that nitrogen liberated by the chemical changes taking place during the burning of the powder reacted with the metal lining of the gun and formed compounds which play a considerable part in the erosion of the bore, and it was at that time that he first offered this theory to his immediate superiors at that place. While this supposition was rejected at the time, the work of the past three years has done more to prove than disprove this point. In view of the extreme brittleness and fragility of the surface of steel after exposing it to the action of nascent nitrogen at elevated temperatures it has been and is the firm belief of the writer that this action goes on within the bore of guns and that the fragile substance formed, be it iron nitride or not, is, owing to its nature, readily swept away by the physical forces so well known. It therefore is believed that when attempts are made to reduce erosion to a minimum this point should not be overlooked and if at all possible a steel should be specified which has as high a resistance to the action of nascent nitrogen as is possible and at the same time meet the necessary physical requirements. The later work of Wheeler, previously referred to, adds a great deal to the strength of this theory. Erosion is therefore believed to be caused by chemical as well as physical and thermal changes.

Determination of Nitrogen Oxides in Processess for Nitrogen Fixation

BY GUY B. TAYLOR

MANY investigators in the field of electrical discharges through gases have need for an accurate method of analyzing gases for nitric oxide. In many cases these investigators are not trained chemists, but may be physicists or electrical experts. In casting about for a method suited to their purpose, they naturally seize upon the obvious one of absorbing the nitrogen oxides in an excess of standard sodium hydroxide solution and titrating the excess alkali with standard acid after absorption. This method in the hands of an inexperienced analyst will unquestionably yield inaccurate results. The purpose of this note is to describe a simpler method, one not so likely to lead to errors as the alkaline absorption method.

Ehrlich and Russ¹ showed that nitrogen peroxide is quantitatively converted to nitric acid by hydrogen peroxide solutions. This reaction serves as the basis of the proposed method which is carried out as follows:

The gas is sampled by allowing it to fill an evacuated glass bottle provided with a glass stopcock. For arc-furnace gases a two-liter bottle is convenient. The volume of the bottle must be known as well as the previous degree of evacuation. If an excess of oxygen is not normally present in the gas to be sampled, oxygen gas must be added to the sample to convert nitric oxide to nitrogen peroxide. After filling the bottle to atmospheric or some other exactly known pressure and ascertaining the filling temperature, introduce 25 to 50 c.c. of 1.5 per cent hydrogen peroxide solution and shake until the reddish color of NO₂ disappears. Let stand at least five minutes and shake again. Then titrate the acid solution in the bottle with N/10 sodium hydroxide, using methyl orange as the indicator.

Practically all hydrogen peroxide solutions are acid in reaction. To prepare the reagent for the analysis, dilute the commercial 3 per cent peroxide with an equal volume of water and neutralize with N/10 sodium hydroxide, using methyl orange indicator.

To calculate to per cent nitric oxide, let

a = c.c. N/10 alkali used.

v = volume of bottle in c.c.

b = barometer in millimeters of mercury, corrected.

p = pressure in bottle before sampling, millimeters of mercury.

t = temperature of gas sample, deg. C.

Then

$$\frac{2.24 a}{v \left(\frac{b-p}{760} \right) \left(\frac{273}{273+t} \right)} \times 100 = \text{per cent NO}$$

This formula holds for low concentrations of nitric oxide, say up to 3 per cent NO, where the volume change due to formation of nitrogen peroxide may be neglected. To convert per cent NO to grams HNO₃ per cubic meter of gas at standard temperature and pressure (0 deg. C., 760 mm.) multiply by 28.

In many cases the temperature of the gas at the point of sampling is considerably higher than room temperature, in which case it is not practicable to determine the temperature of the gas in the bottle at the moment of closing the stopcock. In such cases proceed as follows: First, introduce the peroxide reagent with a rubber

tipped pipette so that no air enters. After absorbing the nitrogen oxides, allow a measured volume of water to enter the bottle until the residual gas is at atmospheric pressure. Titrate as described above. In addition to the previous notation, let

w = vapor pressure of water at t deg. C.

v' = volume of peroxide plus water introduced into the bottle. Then

$$\left[(v - v') \left(\frac{b-p-w}{760} \right) \left(\frac{273}{273+t} \right) + 2.24 a \right] \times 100$$

gives the percentage of NO.

The advantage of the above-described method lies mainly in the fact that only one standard solution is required and there is no trouble from bleaching of indicators by nitrous acid. Most indicators suitable for titrating in the presence of nitrites are sensitive to CO₂. This means that in the alkaline absorption method the standard sodium hydroxide solution must be prepared free from carbonates and carefully protected from the air after its preparation. Another serious source of error that an inexperienced investigator is likely to encounter is a mathematical one. The tendency is to use five or six or even ten times as much alkali for absorption as is neutralized by the gas, with the result that burette errors and errors in the factors of solutions are magnified. There is no possible advantage in any excess alkali above that required to keep the absorbing solution barely alkaline. Such excesses of alkali may lead to serious misinterpretations of results, when, as is often the case, conclusions are based on a difference of 2 or 3 c.c. of the standards.

Experimental Station,
Wilmington, Del.

France the Richest European Country in Iron Ore

It may not be generally known that France is the richest country in iron ore in Europe, and that the United States is the only country in a position to challenge her for the leading position of the world. With the restoration of Alsace-Lorraine, it is estimated that the French output will be 45,000,000 tons of iron ore a year, of which 17,000,000 tons will be exportable.

The successful organization of the export trade has now been brought about by the Comptoir Siderurgique de France, which has absorbed the Comptoir des Poultries and the Comptoir d'Exportation des Produits Siderurgiques. The large forges or steel works, by means of a combination known as the Committee of Forges, are securing increasing interests in iron mines, waterpower, coke ovens and mechanical engineering shops. In order to obtain the best results in foreign trade there has been created an industrial unity comprising the mine, the forge, the workshop and the bank. The opportunity has been taken by important French firms to secure in the markets of the world the position formerly occupied by organizations of a semi-industrial and semi-trading character, such as the Metall-Gesellschaft.

Engineering undertakings of all kinds have for many years been chief factors in French expansion abroad—particularly in Asia Minor, Russia and South America. A great many South American ports are under the management of French enterprises. The Maison Fougere Freres and the Societe Generale d'Entreprises have between them executed contracts of a total value of 950,000,000 fr. and are now making elaborate plans for the extension of their foreign business.

Need of Professional Solidarity Among Chemists*

A Succinct Review of the Status of the Chemists as Related to the General Welfare of Their Profession, and as to Their Duty to the Community and the Nation

By H. C. PARMELEE

THE United States needs a consciousness of chemistry as a factor in its national welfare, and the only man who can create that consciousness is the chemist. The war laid the foundation for this achievement. It remains for the chemist to build the superstructure, not only in the public interest but also for the advantage of professional solidarity. The immediate aim thus seems to be twofold, but the ultimate accomplishment is single in its purpose—the reaction of chemical thinking on the life and activities of the people.

It is safe to say that the part played by the chemist in the World War brought him into public prominence as did none of his previous scientific and technologic achievements. The reason is that his services touched directly the great mass of the people. He came out of the seclusion of his laboratory and stood forth as a fellow citizen, specially trained to meet a need that was insistent, sudden and unexpected. His performance commanded the respect of soldier and civilian alike. He "arrived" with almost unprecedented efficiency and became a factor of prime importance. His work stood out as eminently practical and was shorn of much of the mystery that had previously surrounded him in the public mind. In fact the public suddenly became conscious of the chemist, just as it was conscious of the surgeon as a necessary adjunct to the army.

But the public had long been conscious of the surgeon in its civil life as a necessary adjunct to peaceful pursuits. Why had it not so recognized the chemist? It was not because he had not played an important part in the daily life of the nation, for he had. For years he had been controlling important industries—the manufacture of steel, the production of foodstuffs, the winning of gold and silver from their ores, the manufacture of medicines, the purification of municipal water supplies, the making of paper and ink, the application of fertilizers, the production of dyes, the preparation of salt, soap, starch and sugar. For years he had been thus close to the public interest and yet had failed to gain the recognition that was accorded to other professionals.

A NEEDED PUBLIC CONSCIOUSNESS RELATING TO CHEMISTS WROUGHT BY THE WAR

The nature and importance of the chemist's work were comparatively unknown to the great mass of the people, for whom his queer apparatus and strange solutions and smelly laboratory were shrouded in mystery.

The war wrought a sudden change. The chemist became a marked man; and while he was drafted, it was not into the infantry, but into the laboratory and plant for the production of munitions. Much of his work

was the same as it had been in times of peace—the production of steel, food, medicine, metals, fertilizers, soap. The principal difference lay in the channels to which the products of his ability were diverted. He gained more publicity and greater recognition; there was no longer quite so much mystery about the nature of his services.

It is safe to say that before the war the average citizen, on discovering that his neighbor was a chemist, would say, "Oh, yes," in a hazy sort of way, and then either change the subject or inquire, "Well, just what do you do?" And if the reply indicated, for example, that the chemist worked in the laboratory of a railroad company or a packing house, the mystery would only be deepened. But let the same man casually learn that his neighbor was a lawyer or a doctor, and immediately he would understand that man's place in society and his relation to the community; and it would matter not whether the lawyer or doctor were employed at a smelting works or a sugar factory, the average citizen would understand the nature and value of his services. And this because there was a public consciousness relating to doctors and lawyers which had not yet developed regarding chemists and chemistry.

PROFESSIONAL SOLIDARITY FOSTERED BY SELF-CONSCIOUSNESS

Granting that the chemist is no longer an unknown quantity in the public mind and that the importance of his part in the general scheme of things is recognized and admitted if not fully understood, the next step is the creation of professional solidarity among chemists by fostering a modest self-consciousness of their relation to society and their duty to the community and the nation. The chemist may not again retire to the obscurity of his laboratory and plant. He has certain abilities and ways of thinking that can be turned to good account in public affairs. He possesses knowledge of incalculable and practical value and benefit to the public, and the public is entitled to it. And more: if the chemist is to be satisfied with the conduct of business and government, he must apply thereto his qualities of precision, accuracy, efficiency, integrity and all other mental products of his education and training, or else refrain from criticism of those who lack his knowledge and point of view. Like the engineer, his preparation for professional work "makes him exact, precise, honest, efficient, unshackled by tradition, aggressive in attacking a problem, sound in analysis and judgment, and fearless in execution." These qualities are quite as useful for citizenship and government as for scientific pursuits, and those who possess them are obligated

*Excerpt of an address delivered before the New York alumni of Alpha Chi Sigma, and published in *The Hexagon*, September, 1920.

"The Engineer and His Thinking," *CHEM. & MET. ENG.*, Aug. 18, 1920, p. 265.

to exercise them in the public interest. And so it is now incumbent on the chemist to develop a consciousness of his duties and obligations to society. That self-consciousness will draw the members of the profession together and ultimately give them a sense of power that comes with unity. Solidarity, community of interest, will not be achieved if the chemist attempts to remain in "splendid isolation." In fact, neither he nor his profession will flourish, nor will he gain public recognition as a member of a great profession if he remains in isolated independence. The chemist must change his way of thinking of himself as an individual and look upon himself as a member of an important profession.

WHAT PROFESSIONAL SOLIDARITY CAN ACCOMPLISH

We may take a lesson in ways and means to accomplish this from another profession of marked solidarity. Lawyers are organized in bar associations everywhere, and through these associations the voice of the profession becomes articulate. The public recognizes a pronouncement by a bar association on any subject of public welfare as a professional expression of opinion from a group of men qualified to pass technical judgment. Influence is thus exerted which would be impossible for any individual to put forth. The effect is cumulative: a sense of professional solidarity leads the bar association to speak with authority; the public is impressed by the weight of organized opinion and learns to respect it. This gives the association a new sense of power and responsibility and encourages it to assume leadership which the community, in turn, finally accepts as a matter of course. The relations become mutually advantageous. But the point to be observed is that the entire development had its inception in the consciousness of a group or class of men, due to similar training and habits of thought. So it must be with the chemist. To borrow a phrase from our labor friends, he must acquire "class consciousness," or, as it is better phrased, professional solidarity.

THE CHEMIST MUST IMPRESS THE PUBLIC WITH HIS OWN WORTH

It has often been humorously remarked that the lawyer has gained his position of professional prominence in the public mind by simply assuming it—by talking himself into it. There is quite as much truth as humor in the statement. Oratory is part of his stock in trade and he uses it for advertising purposes. And advertising may not be neglected, especially when promoting a new venture. If the chemist is to rise to a position of professional prominence and recognition he must, to use a modern commercial phrase, "sell himself" to the public. Publicity begins at home. If the chemist does not impress the public with his own worth, nobody will do it for him, at least not to the extent of creating that chemical consciousness which we want to see in the public and that sense of solidarity which we want to create among the chemists themselves. Advertising is essential. A man in the dark may know where he is, but nobody else does. He needs an illuminated sign. Likewise the chemist is a worthy citizen, but if he carefully refrains from collective action and expression nobody will be cognizant of his importance or gain the benefit of his knowledge. Lawyers assume leadership in government, acquire places on the directorates of large corporations, and otherwise gain distinction in public and private life. They and their opinions find favor with

financiers and industrial leaders. The same road to distinction is open to the chemist if he first gains that sense of professional fellowship and community of interest, and then impresses the public with his ability for leadership. There is no inherent reason why he cannot be recognized by bankers and business men as a professional necessity equally with the lawyer.

AN APPROPRIATE MACHINERY FOR THE REALIZATION OF THE CHEMISTS' PROFESSIONAL SOLIDARITY

There remains, then, the consideration of the machinery for accomplishing this professional solidarity. Some form of organization or association immediately suggests itself, but a new addition to our already long list of societies does not make a favorable appeal. True, the engineers, who have been confronted with this same problem of crystallizing a professional sense out of the prominence and importance which the engineer gained in the war, have deemed it advisable to organize new societies; but it is doubtful if this is necessary for the chemists. Their technical society already is functioning in this respect to a certain degree, and that activity can be increased. In the meantime Alpha Chi Sigma offers a fertile field for the cultivation of the ideas herein expressed. Composed of men who presumably have a lively sense of fellowship as well as exceptional technical ability in chemistry, it affords a culture medium for the propagation of the thoughts that are beginning to find expression. Through its publication, *The Hexagon*, it should be possible to disseminate that particular kind of advertising which will demonstrate the importance of the chemist as a citizen and his relation to society, thereby fostering the professional sense and gaining public recognition. The fraternity should have some definite activity, for without it there can be no binding force to hold it together and make it useful. In helping to create this professional solidarity it would be doing the very thing that would make the fraternity flourish as a graduate or alumni organization—and that is where most alumni organizations fail, in a lack of common interest. If the alumni of Alpha Chi Sigma were to get the spirit of the new professional life that is now opening before chemists, they would leaven the whole body of technologists in a short time.

Restriction of Rubber Production Agreed Upon

At the beginning of 1920 the price of rubber in London was 2s. 11d. (71c. at normal exchange) a pound, from which it fell to 1s. 5½d. (35c.)—a figure very little above the average producing costs. Owing to the absence of American and British demand, stocks in London steadily increased, and finally, a month or so ago, the Rubber Growers' Association (London) recommended that production should be reduced by 25 per cent of the estimated normal monthly output, either by resting one-quarter of the tapping area or, preferably, by alternate-day tapping over one-half of the tapping area. If 70 per cent of the producers agreed, this scheme was to be put into operation Nov. 1.

The suggested scheme of restricted output has now received the necessary support, and the plan went into operation on Nov. 1, 1920. Under the agreement, the 25 per cent curtailment of production will operate until December, 1921. It is pointed out that while the output of rubber has increased five times since 1912, the price has fallen to less than one-fifth of the quotations then ruling.

Putting the Responsibility on the Student

BY JOSEPH W. RICHARDS

... care being taken to convey instruction in such a shape as not to make it compulsory on them to learn; because no trace of slavery ought to mix with the studies of the freeborn man.—PLATO.

AMERICAN institutions of higher learning are conducted entirely too much on the kindergarten plan and far too little on the principle of letting students work of their own volition. In the primary, secondary and grammar schools the hapless student is the object of a rigid system of "must," which leaves him no alternative but to work his hardest at the task imposed. In the high school things are much the same; lessons are assigned in a textbook, recitations are the principal exercise in the class room, and a rigid system of scoring absences insures that no student can be absent more than a specified number of times without being disciplined.

Our colleges, technical schools and universities continue this mechanical forcing of the student to his work. Every day has its appointed tasks, every hour is full of responsible duties, every precaution is taken that the student do at least the minimum amount of work before being passed for graduation. In fact, his teachers largely take upon themselves the burden of making him work; if a goodly proportion of the class does not attain the pitiful minimum of 60 per cent, the teacher's conscience begins to hurt him—he has not made them work hard enough.

Under these conditions, which prevail quite generally, what opportunity has the student to learn his own responsibility to keep himself at work? With no option but to attend and grind, how can he feel any right sense of the great opportunities which are his? He is forced to do what he ought to be happy to do of his own volition, and his better nature rebels at the compulsion. But his rebellious spirit finds no chance to realize its ideals; he is in the grip of the machine, he must do the work assigned and forced upon him, and he does it often with a discontented attitude, because he is made to do it.

What is the remedy? It is undoubtedly to put university students on their own responsibility, so that they can practice keeping themselves at their work. Do not make them do anything; let them make themselves do everything. You cannot teach a boy to use a knife without giving him one to use; he will probably cut himself in learning how, but give it to him you must. It is the same with the student's responsibility to bear his own burdens and to keep himself up to his work; the compulsion to work must be removed before the student can learn to take care of himself. Keep up the compulsion always, and you are robbing him of the chance to learn how to order and guide his own powers and his destiny; put the responsibility on him, and you are giving him the chance to learn to bear it.

The conclusion just stated may sound revolutionary and visionary to those so set in the old ways that they cannot see over the fences hedging in their narrow paths; but it works! Try it. Take no absences, hear no set recitations, stop treating university students like schoolboys who have to be made to work, and treat them like men who know what they are at college for and mean to get it.

Then eliminate the weaklings and the neglectful by occasional examinations, fairly given and carefully read and assessed. If a student shows that he has not been doing what he should and what he knew was expected from him, give him his medicine, drop him out after perhaps one warning; he has eliminated himself. This leaves in college the earnest and capable and the workers. They are all to whom the institution owes any obligation. Their work will progress better and more profitably by reason of the elimination of the unfit.

It is no proper part of the duty of a university teacher to make a student work. Lead the horse to water, but you cannot make him drink; it is folly to try. Tell the student of his great opportunities, spread the feast before him, but do not try to force him to eat. By this policy it is possible to eliminate from our American colleges and universities the indifferent, the unwilling, the "deadwood" of our classes, and to confine our further efforts to the inquisitive, the willing, the seekers after knowledge, who will work as hard as anyone could wish, without any compulsion.

This is the teachers' as well as the students' paradise—a university where no compulsion exists and students bear themselves the responsibility of working, led by the helpful advice and sympathetic counsel of their co-workers—the teachers.

The Theory of Gas-Scrubbing Towers With Internal Packing

BY W. B. VANARSDEL

IN A RECENT article¹ on this subject by F. G. Donnan and Irvine Masson they first give a brief review of the rather scanty literature on the theory of gas scrubbing and then proceed to give attention to the results of Adeney and Becker,² which show that in the case of gases which obey Henry's solubility law, the rate of solution at any moment is proportional to the unsaturation of the liquid at that moment. The following is a brief summary of their calculations.

If m the concentration of absorbable component in the gas phase and n the corresponding concentration in the liquid, the rate of solution is proportional to

$km - n$, where $k = \frac{n}{m}$ at equilibrium; that is, k is

the Henry coefficient. The rate of solution depends also on a coefficient k_d , which the authors call the *dissolution coefficient*, and they remark: "Under strictly specified conditions this coefficient will be a constant quantity, but in general its value will increase with the degree of relative motion of gas and liquid and the degree of turbulence in both. The part played by the very thin 'stagnating layer' in hindering the exchange of heat energy or matter between different phases is well known to be a decisive factor in the design of heat interchangers and recuperators, furnaces, dissolvers, extractors, etc., and the thickness of this layer is diminished by increase of relative motion of the phases and by rupture of this layer due to the splashing of drops. We may term k_d a *dynamical coefficient*."

In developing the theory of gas absorption in counter-current towers on this basis Donnan and Masson con-

¹J. Soc. Chem. Ind., vol. 39, p. 236T (1920).

²Proc. Roy. Dublin Soc., 1918-19, vol. 15 (N. S.), pp. 385, 609.

sider only the simplest case, by making the following assumptions:

1. Temperature kept uniform and constant throughout the tower.

2. The volume percentage of the absorbable gas constituent is supposed fairly small, so that volume changes due to its removal may be neglected as a first approximation.

3. The solubility of the main gas constituent is neglected.

4. The vapor pressure of the scrubbing liquid is supposed to be such that volume changes due to saturation of the gas with this vapor may be neglected as a first approximation.

5. The flow of both gas and liquid is supposed to be uniformly distributed over every cross-section of the packing.

6. The wetted area of the sides of the tower is neglected in comparison with the wetted area of the packing.

7. The absorption is a simple "physical" absorption—i.e., one not complicated by relatively slow chemical reactions in either gas or liquid.

The following symbols are used, calling the absorbable constituent of the gas X :

M_1 = grams of X per cu.m. of entering gas.

M_2 = grams of X per cu.m. of issuing gas.

m = grams of X per cu.m. of gas at level x in the tower.

N_1 = grams of X per cu.m. of entering liquid.

N_2 = grams of X per cu.m. of issuing liquid.

n = grams of X per cu.m. liquid at level x in the tower.

x = distance measured vertically downward from top of packing.

h = total height of packing.

V_g = flow of gas in cu.m. per minute.

V_l = flow of liquid in cu.m. per minute.

S = area of cross-section of tower (supposed uniform).

k = Henry coefficient as defined above.

k_p = "coefficient of packing," area of interface between gas and liquid, in sq.m. per cu.m. of packing.

$f = \frac{V_g}{V_l}$ = "flow ratio."

$r = \frac{M_2}{M_1}$ = ratio of absorption.

k_s = dissolution coefficient as defined above.

The authors point out that the coefficient of packing, k_p , must also be considered as a dynamical coefficient, since its value does not depend alone on the average wetted surface of the packing units, but may be due in large part to drops of liquid, in the form of drips and splash. It probably rises as the volume of liquid increases, but reaches a maximum and perhaps thereafter decreases when the flow becomes large enough to form small continuous streams.

Considering the element of volume between the heights x and $x + dx$ in the tower, the following fundamental equations may be formed:

$$k_p k_s (km - n) dx = V_g dm \quad (1)$$

$$n = fm - (fM_2 - N_2) \quad (2)$$

When these equations are combined, the resulting differential equation integrated and the limiting conditions substituted, either of two forms results:

$$\text{Log}_e \frac{(k-f)m + (fM_2 - N_2)}{kM_2 - N_2} = \frac{k_1 k_s S (k-f)}{V_g} x \quad (3)$$

$$\text{Log}_e \frac{(k-f)M_1 + (fM_2 - N_2)}{kM_2 - N_2} = \frac{k_1 k_s S (k-f)}{V_g} h \quad (4)$$

If $N_2 = 0$, as will often be the case,

$$\text{Log}_e \frac{k}{kr} = \frac{k_1 k_s S (k-f)}{V_g} h \quad (5)$$

The authors also write the simplified forms which result from assuming that M_1 is zero or negligible, or that the liquid issuing from the base of the tower is in equilibrium with the incoming gas.

In their conclusion it is shown that these equations give in a quantitative manner the way in which a high absorption efficiency depends on:

1. High interfacial area between gas and liquid.

2. High relative motion of gas and liquid (within limits).

3. High degree of turbulent motion in one or both phases.

4. Sufficient rate of flooding to secure the maximum drip effect.

SIMPLIFICATION BY USE OF HEAT INTERCHANGER FORMULÆ

These calculations are of great interest to all engineers who have anything to do with gas absorption on a large scale. For this reason it seems to the writer that attention might well be drawn to some simple consequences of the theory. The labor of calculation can be greatly diminished and the results become more significant when it is realized that the gas-scrubbing tower can be rigorously compared to a heat interchanger. The weight, W , of absorbable constituent which passes from one phase to the other may be determined from:

$$W = Ak_s C_m Z \quad (6)$$

where A is the area of interface between liquid and gas, k_s a constant for the particular tower and manner of liquid and gas distribution, analogous to the constant of "conductivity" used in heat-exchange calculations, C_m a "mean concentration difference" analogous to the "mean temperature difference," and Z the elapsed time. Now on the basis of the expression derived by the authors for the variation in concentration with the level in the tower (counter-current flow) it is easy to deduce a value of C_m which will make equation 6 true. This value is as follows:

$$C_m = \frac{(kM_1 - N_2) - (kM_2 - N_1)}{\log_e \frac{kM_1 - N_2}{kM_2 - N_1}} \quad (7)$$

where M_1 is the concentration of the entering gas, M_2 that of the issuing gas, N_1 that of the entering liquid, N_2 that of the issuing liquid and k the "Henry constant," according to which, at saturation, $kM = N$. In case the absorption does not follow Henry's law, but an empirical relation between M and N is known, it is possible again to define C_m in concentration terms only, but its form is almost certain to be much more complicated.

The perfect analogy of C_m to the "logarithmic mean temperature difference" familiar in the heat calculations is obvious. The tower-constant, k_p , thus receives a more definite and suggestive meaning because of the familiarity of the heat-interchanger problem.

Determination of Atmospheric Impurities—I

A Description of the Nature of Atmospheric Impurities. With Special Reference to Salt Lake City, Utah, Conditions—Methods and Apparatus Used for Their Determination—Results Obtained—Physical Character of the Solid Atmospheric Impurities

BY OSBORN MONNETT

EXACT knowledge of the nature and amount of atmospheric impurities is of considerable value in carrying out plans for smoke abatement. Ringelmann chart readings show the density of smoke as it leaves the stack and serve to show the relative importance of different classes of smokes and the amount of smoke sent into the atmosphere. They do not, however, show how much of this smoke actually stays in the city. Local topographical and weather conditions affect the nuisance profoundly. Thus Salt Lake City, whose gross coal consumption and smoke production are low compared with many other cities, has as aggravated a smoke nuisance as any city in the country. This is due to its location in a region of low wind velocity, in a valley almost surrounded by mountains. Another city of equal size and equal coal consumption but situated in a region of higher wind velocity might show identical Ringelmann chart figures and yet have very little smoke nuisance. It is evident, then, that figures showing the concentration of soot and other impurities in the atmosphere of the city are needed.

Such data show the sources of pollution in order of importance and tell the engineer in a very definite way what he must contend with. They also serve as a standard of reference for future years to determine with accuracy the progress made by smoke abatement measures. Conditions existing in cities today give rise to pollution of the atmosphere with soot and fine ash from burning of coal, with dust from traffic and industrial operations, and with small amounts of poisonous gases from industrial plants and coal fires. These all add to the "smoke" nuisance and contribute their share to making city air more or less detrimental to the health of the inhabitants and injurious to property.

NATURE OF ATMOSPHERIC POLLUTION

Pollution of city air is of several kinds:

1. Soot from burning of coal in industrial operations, large heating plants and domestic stoves and furnaces. This soot is the largest source of harm and annoyance. It is a mixture of varying proportions of carbon, tarry products of coal distillation, sulphur acids and ash. Taken in with the air we breathe, it lodges in the throat and nasal passages, and the finer particles get into the lungs. The presence of tar and sulphur acids makes it an active irritant and predisposes the breather to throat trouble and pneumonia. This soot soils and damages our clothing, curtains and woodwork and injures vegetation. Smoke from high-pressure plants tends to be high in ash and contains little tarry matter. Smoke from low-pressure plants and domestic stoves

and furnaces is higher in tar acids and oily products of combustion and is more detrimental to health, property and vegetation.

2. Gases from burning of coal, from manufacture of industrial products and from decay of organic matter. Among these are sulphur dioxide, sulphuric acid, hydrogen sulphide, ammonia, chlorine, nitrogen acids and carbon dioxide. Of these only sulphur dioxide formed from the burning of coal and sulphuric acid formed from the sulphur dioxide by action of air and water vapor are usually present in more than negligible quantities. These are both poisonous and corrosive gases. In the West considerable litigation has taken place between farmers and smelters as a result of damage done to crops and live stock by sulphur dioxide from the roasting of ores. The relation of sulphur dioxide to the Salt Lake problem will be discussed fully in a later paragraph.

3. Dust of non-fuel origin. This includes considerable quantities of fine dust from industrial and building operations, paving dust from traffic, pollen, spores, decayed organic matter and soil. Such dust is as a rule less harmful to health and property. In Chicago it is estimated that 41 per cent of the solids in the atmosphere are of non-fuel origin.

NATURE OF ATMOSPHERIC POLLUTION IN SALT LAKE CITY

There is a very marked seasonal variation in the character and amount of atmospheric impurities in Salt Lake City. In the growing season from April through October the impurities are principally dust of non-fuel origin. With the beginning of the heating season the amount of coal smoke begins to increase until in December and January the city is often hidden in a pall of fog and smoke so dense that it is impossible to distinguish objects at 100-yd. distance. This smoke cloud is seldom pure soot, but is usually mixed with water vapor. The humidity in winter is high and smoke particles act as nuclei for the condensation of water vapor. This makes fogs of more frequent occurrence than if the atmosphere contained no foreign particles. Such fogs are dissipated with difficulty by the sun and may exist without evaporation for a considerable time even though the humidity of the atmosphere is considerably below saturation.

In the winter, when the smoke nuisance is at its height, the atmosphere is remarkably free from dust of non-fuel origin, but contains relatively large amounts of soot and ash from coal fires. Such material, due to its color and fine state of division, is a much greater nuisance, weight for weight, than the coarser and heavier industrial and other dust. A given weight of such soot will soil as large an area of white collar or lace curtain as one hundred times its weight of coarser

EDITOR'S NOTE: This is a chapter of the smoke-abatement report made by the Bureau of Mines in June, 1920, on its work in Salt Lake City, where it had the co-operation of the city and State University authorities. Published by permission of the Director of the Bureau of Mines.

dust. Hence although, as shown later, the actual weight of solid matter in the atmosphere is not extremely high, the actual nuisance in terms of soiling and damaging fabrics and architecture is very bad.

METHODS USED TO DETERMINE ATMOSPHERIC IMPURITIES

Three general methods have been used in the past for estimating the quantity and kind of solid matter in the atmosphere.

1. Filtration methods, in which a known amount of air is filtered through a paper or cotton wool filter. The weight of solid matter entrained by the filter may be expressed as weight per unit volume of air or the relative blackness of the filter may be used as a measure of the amount of solid matter present. Filters are examined microscopically to determine the character of solids and their relative amounts.

2. Counting methods, in which a known volume of air is blown against a prepared glass slide which is subsequently examined microscopically both as to number and character of particles. Results are expressed as to number of particles per cubic centimeter.

3. Settling methods, in which vessels of known dimensions are set up in places away from direct contamination by nearby stacks and the soot allowed to collect for a month or more. The deposit is subsequently weighed and examined chemically and microscopically. Results are expressed in tons of deposit per square mile per annum.

All of these methods give valuable information and none of them tells the whole story in itself. The filtration method, in which the actual weight of solid material per cubic foot is obtained, gives an exact figure which may be compared with results in other cities. On the other hand, it tells little of the character of the

FIG. 1 APPARATUS FOR ATMOSPHERIC ANALYSIS

solid matter, and the presence of large particles of high specific gravity gives a high figure which may not indicate the actual degree of smoke nuisance. Several hours are needed for securing a weighable amount of solid matter. The procedure gives only an average result.

The method in which the number of particles in a given volume of air are counted allows instantaneous samples to be taken and tells something of the character, size and shape of the particles.

The soot fall method makes possible the collection of sufficient material for analysis and gives a basis for calculation of the amount of combustible matter discharged per annum. However, the amount of matter of other than fuel origin which finds its way into the jars is considerable and it is a difficult task to separate the constituents.

It seems best, then, to use if possible all these methods in order to definitely classify the solid material in the air as to nature and amount. Such results are of great value in expressing in a fairly exact way the extent of the smoke nuisance and serve as a standard by which the nuisance may be compared in successive years and with that prevailing in other cities.

For estimating gaseous impurities standard analytical procedure may be employed and accurate results obtained. The amounts of the various impurities are expressed in milligrams gas per cubic meter of air or in parts gas by volume per million parts air.

DESCRIPTION OF APPARATUS AND METHODS EMPLOYED

The apparatus employed in determining the amount of solid matter and other impurities in a given volume of air was essentially the same as used by the Chicago Smoke Abatement Committee.¹

The analytical train as shown in Fig. 1 consists of:

1. Filtration apparatus.

2. Bottle for carbon dioxide determination.

3a. Absorbing solution of sodium hydroxide for determination of nitrous acid, chlorine and sulphur acids.

3b. Absorbing solution of hydrochloric acid for determination of ammonia.

The apparatus used for determining sulphur dioxide in the atmosphere will be described later.

A gas meter was placed between the filtration apparatus and the rest of the train to record the amount of air aspirated through the filter and train. A 6-volt motor and storage battery operating a rotary pump served to draw air through the train. About 10 cu.m. of air was drawn through the apparatus during the test, which lasted about six hours.

FILTRATION APPARATUS

The apparatus as shown in the figure was arranged to hold a paper filtration thimble 43 mm. in diameter by 123 mm. long and to keep the thimble against the wind during the test in order to have duplicable conditions throughout. The collecting tube of the apparatus swings on a ball bearing and is sealed airtight with a mercury seal.

Considerable trouble was experienced in accurately weighing the paper thimbles. They were found to be extremely hygroscopic, changing several tenths of a gram in weight from day to day owing to changing humidity. In the procedure finally used the thimbles were dried in a constant temperature oven at 50 deg. C. for one week. Air dried over sulphuric acid was passed constantly through the oven. The thimbles were then allowed to cool in a dessicator over sulphuric acid and weighed in an aluminum container having a tight fitting screw top. This procedure was repeated from day to day until the weight was constant to 1 mg. Better accuracy than this could not be obtained. After use the thimble was again dried to constant weight.

Results were calculated in milligrams solids per cubic meter of air.

DETERMINATION OF CO₂

The Pettenkofer method was employed.

Solutions Used. 1. Oxalic acid of strength such that 1 c.c. = 0.25 c.c. CO₂ at 0 deg. C. and 760 mm. pressure.

¹Report of the Chicago Association of Commerce Committee of Investigation on Smoke Abatement and Electrification of Railway Terminals, W. F. M. Goss, chief engineer. Rand, McNally & Co., Chicago, 1915, pp. 40-18.

Pure recrystallized oxalic acid ($\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$) to the amount of 1.407 g. was dissolved in one liter of water and kept in a brown bottle. The strength of this solution is checked frequently by titration with N/20 sodium hydroxide.

2. Barium hydroxide of strength such that 50 c.c. baryta solution neutralizes 30 to 40 c.c. oxalic acid solution. This solution is prepared from a saturated solution of barium hydroxide by dilution with water. It was kept in a bottle having a soda lime tube and 50 c.c. overflow pipette.

3. Phenolphthalein solution. One gram of pure phenolphthalein is dissolved in 100 c.c. of 86 per cent alcohol. Two drops of this solution are used in the titration.

Procedure.—A wide-mouthed bottle having a volume of about four liters was used. This was placed in series with the analytical train and air aspirated through it for half an hour. The bottle was then removed from the train, corked with a rubber stopper in the center of which was a hole plugged with a small rubber stopper. The small stopper was then removed, 50 c.c. of standard baryta solution was run in from a pipette and the stopper replaced. The bottle was then shaken at intervals for twenty minutes so that the liquid wetted the sides completely. The excess baryta was then titrated with standard oxalic acid. A blank was also run on 50 c.c. of the baryta solution. Knowing the strength of the oxalic solution in terms of CO_2 , the volume of the bottle, and the temperature and pressure, it was possible to calculate the carbon dioxide present. This was expressed in parts per million of air.

DETERMINATION OF NITROUS ACID, CHLORINE AND SULPHUR ACIDS

Absorbing Solution.—One pound of sodium hydroxide is dissolved in eight liters of water and 400 c.c. of this solution is placed in the absorbing bottle.

Analytical Method for Nitrous Acid.—The solutions used are:

1. Sulphanilic acid. Sulphanilic acid to the amount of 4 g. is dissolved in 500 c.c. of acetic acid, specific gravity 1.04.

2. Alpha-naphthylamine. Alpha-naphthylamine to the amount of 2.5 g. is dissolved in 500 c.c. of acetic acid, specific gravity 1.04.

3. Standard nitrite solutions. (a) AgNO_3 to the amount of 0.328 g. is dissolved in hot distilled water in a liter flask. Pure NaCl to the amount of 0.3 g. is added and when cold the solution is made up to a liter with distilled water, thoroughly shaken and the precipitate allowed to settle. (b) 100 c.c. of solution a is diluted to one liter. (c) 10 c.c. of solution b is diluted to one liter. 1 c.c. of solution c = 0.001 mg. HNO_2 .

The procedure is as follows: Dilute to 50 c.c. 5 to 25 c.c. of the NaOH solution from absorption bottle, 15 c.c. of acetic acid, 2 c.c. each of No. 1 and No. 2. This is compared in a calorimeter against a standard solution made by adding 10 c.c. of solution c to 30 c.c. acetic acid, 150 c.c. of unused NaOH solution, 5 c.c. of No. 1 and 5 c.c. No. 2. A blank must be run on the NaOH solution.

Analytical Method for Chlorine.—The per cent of chlorine in Salt Lake air was too small to permit of estimation by the usual gravimetric or volumetric methods. Recourse was had to nephelometric estimation of the density of the precipitate of silver chloride.

The solutions used are:

1. Standard NaCl solution. Dissolve 0.165 g. pure fused NaCl in one liter of water. 1 c.c. = 0.1 mg. chlorine.

2. Standard NaCl solution. Dilute 10 c.c. of solution No. 1 to one liter in a graduated flask. 1 c.c. = 0.001 mg. chlorine.

3. Approximately N/100 AgNO_3 .

4. Approximately N/10 HNO_3 .

The procedure is: To 30 c.c. of NaOH solution from the absorption bottle are added 10 c.c. of N/10 HNO_3 and 10 c.c. N/100 AgNO_3 . The solution is heated for thirty minutes at 50 deg. C.

A standard is prepared by adding to 110 c.c. of unused NaOH solution 10 c.c. NaCl solution No. 2, 40 c.c. N/10 HNO_3 , 40 c.c. N/100 AgNO_3 , and heating for thirty minutes at 50 deg. C.

These are compared in a nephelometer of the Kober type. A blank must always be run on the NaOH solution.

Analytical Method for Sulphur Acids. Just neutralize with conc. HCl 200 c.c. of NaOH solution from the absorption bottle, add 5 c.c. HCl in excess, add a little bromine water and boil the solution until the color is dispelled; add 25 c.c. of 10 per cent BaCl_2 solution and heat the solution on the water bath for one hour. The solution is then filtered and the paper ignited and weighed.

DETERMINATION OF AMMONIA

Absorbing Solution.—Dilute 20 c.c. of concentrated HCl to one liter. Eight liters of this solution is made up at a time.

Analytical Solutions.—There are two of these:

1. Standard NH_4Cl solution. Place 3.141 g. dry NH_4Cl in a liter flask and make up to one liter with distilled water. Dilute 10 c.c. of this solution to one liter with NH_4 -free water, 1 c.c. = 0.01 mg. NH_3 .

2. Nessler's solution. Dissolve 50 g. KI in smallest quantity of cold water. Add a saturated solution of HgCl_2 until a faint show of excess is indicated. Add 400 c.c. of 50 per cent KOH solution. Filter through asbestos on a Büchner funnel and make up to one liter.

The procedure is: Place 50 c.c. of the HCl solution in a Kjeldahl flask and add 20 c.c. 1 : 1 KOH and 80 c.c. NH_4 -free water. Distill 100 c.c. into a Nessler tube and add 2 c.c. Nessler's solution. This is compared in the calorimeter with a standard of suitable strength made from the NH_4Cl solution.

METHOD OF DETERMINING SULPHUR DIOXIDE

A very sensitive method for determining small amounts of sulphur dioxide in air has been developed by A. E. Wells² in connection with the work of the Selby Commission. This method was used to determine the amount of sulphur dioxide in the air of Salt Lake during December, 1919, and January and March, 1920.

A description of the method and apparatus used, essentially that described by Wells, is given herewith.

Briefly, the method consists in taking samples of the air to be tested by means of evacuated 24-liter bottles containing starch solution faintly colored with iodine. Comparison of this color with that of a blank and addition of iodine solution of known strength until colors

²Holmes, J. A., Franklin, Edward C., and Gould, Ralph A., Report of the Selby Smelter Commission, Bull. U. S. Bureau of Mines, No. 93, 1915, p. 13.

match enables quantitative determination of SO_2 in amounts as low as 0.1 part per million.

The solutions required are:

1. N/100 iodine solution. Place 1.27 g. of c.p. re-sublimed iodine and 5.0 g. of potassium iodide in a graduated flask and make up to one liter with distilled water.

2. N/100 sodium thiosulphate solution. Place 2.48 g.

stoppers containing glass tubes which may be closed by rubber tube and pinch cock as shown. Bottle 2 serves merely as a check and is fitted with single bore stoppers closed with glass plugs.

The titration bottles 3 and 4 are of clear white glass and about 400 c.c. capacity. They are fitted with two-hole rubber stoppers containing a right angle tube extending just through the stopper and a straight tube cut off below the top of the stopper and extending to a point just above the solution. In transferring the solution to the large bottle the finger is placed over the hole in the stopper and the bottle inverted. This transfers the solution without contamination from the air.

The manometer shown (5) is used in determining the pressure in the bottles. The manometer is so calibrated that by noting the temperature and evacuating the bottle to the mark corresponding to this temperature on the manometer scale the amount of SO_2 present may be read off directly in parts per million by multiplying by 2 the number of c.c. of N/500 iodine used. The manometer is calibrated by substituting in the formula

$$M = \frac{273 + t}{0.000813V}$$

Where M = manometer reading in inches, t = temperature in degrees Centigrade and V is the volume of

FIG. 2. APPARATUS FOR DETERMINATION OF SULPHUR DIOXIDE

of pure $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ in a graduated flask and make up to one liter with distilled water.

3. N/500 iodine solution. Run 50 c.c. of the N/100 iodine solution from a pipette into a 250-c.c. graduated flask and make up to the mark with distilled water. The solution is titrated against the N/100 thiosulphate solution; 5 c.c. N/500 iodine solution should equal 1 c.c. of the thiosulphate solution and 1 c.c. of the N/500 iodine solution is equivalent to 0.0224 c.c. SO_2 gas at 0 deg. C. and 760 mm. pressure.

Starch solution. Add 2 g. potassium iodide to 400 c.c. distilled water and heat to boiling. One-half gram

FIG. 3. SMOKE CONCENTRATION AT 344 SOUTH STATE STREET, SALT LAKE CITY, 1919-1920

soluble starch is then added and when this has dissolved the solution is allowed to cool. This solution must be made fresh every day.

Fig. 2 shows the apparatus employed. Bottles 1 and 2 are of 24-liter capacity. Bottle 1 is used in taking the samples. It is fitted with two single bore rubber

FIG. 4. AVERAGE SMOKE CONCENTRATION ALONG SECOND SOUTH STREET DURING DECEMBER, 1919, AND JANUARY, 1920

aspirator bottle in c.c. minus 200 c.c. (the space taken by the starch solution). Values of M corresponding to different temperatures are marked on the manometer scale and labeled with the corresponding temperature. A hand vacuum pump (7) is used in evacuating the bottle.

Procedure.—Place 400 c.c. of starch solution in one of the titration bottles and add iodine solution until the solution has assumed a definite lavender tint. The solution is then divided equally between the two bottles, the plugs removed from the tubulature stoppers in the aspirators, the right angle tubes of the titration bottles inserted in the stoppers and the solution transferred to the aspirator bottles. The titration bottles are then detached, the glass plugs reinserted, and the aspirators shaken for one minute. The solutions are then returned to the titration bottles for comparison.

In case a discharge of color in either bottle is noted, the solutions are mixed, a small amount of iodine solu-

*The formula assumes a constant pressure 25.4 in., an error of about 1.5 per cent.

tion is added to restore the original tint and the operation is repeated until the color of starch solution is not altered by the treatment. The bottles are then SO_2 -free.

The solutions are then put back in the aspirators and the check bottle is closed with glass plugs. The manometer is connected to the upper stopper of the other aspirator and the vacuum pump to the lower. The bottle is evacuated to the point corresponding to the temperature and the pinch cocks are then closed and manometer and pump disconnected.

The top pinch cock is then opened and the air allowed to flow in, the bottle being shaken vigorously as the sample is taken and for one minute after. The blank

FIG. 5. AVERAGE SMOKE CONCENTRATION ON STATE STREET DURING DECEMBER, 1919, AND JANUARY, 1920

bottle is shaken for one minute. Solutions are then transferred to the titration bottles and the color of the determination restored to the same tint as that of the control by addition of N/500 iodine solution from the burette. The number of c.c. iodine multiplied by 2 gives the quantity of SO_2 in parts per million.

In this way 0.1 part per million of SO_2 can be detected. Accuracy is about 10 per cent for concentrations between 0.2 and 1 part per million.

RESULT OF ATMOSPHERIC ANALYSES

Solid Matter. The solid matter in Salt Lake City atmosphere varied during the time of observation (November-April) from less than 0.1 mg. per cu.m. to a maximum of 2.5 mg. per cu.m. From microscopic examination the solid matter so obtained is very largely of fuel origin and is in a very finely divided condition. There is both a seasonal and locational variation in the amount of solid matter present in the atmosphere. The highest concentrations were noted during the months of December and January and in the business district. Lower concentrations were observed during the other months of the year and in the outlying residential districts.

In Fig. 3 concentrations at 344 South State St. have been plotted throughout the time of observation in order to show the seasonal variation. It will be seen that the concentration rises from 0.5 mg. liter early in November to 2.5 mg. liter in January. It falls off to less than 0.1 mg. liter in the latter part of April. These figures are necessarily averaged over the entire day, since six or seven hours was needed to collect a weighable amount of solid material. The months of December and January are the times of minimum temperature and wind velocity, conditions favorable to the production of a large amount of smoke and a slow dissipation of the smoke formed.

Fig. 4 shows the average concentration along Second South St. during December and January. The concentration reaches a maximum in the business district, falling off gradually to a low point at the University.

Fig. 5 shows an east-west concentration variation on State St. during December and January. Again it is evident that the high concentration occurs in the business district.

These curves indicate in a general way the average concentrations. Individual days may vary to a large extent from the curves due to peculiar weather conditions. Sufficient data have been collected to verify in a very striking manner data from Ringelmann chart observations that the largest smoke production is in the center of the city within the zone of highest concentration as shown in Fig. 6.

Carbon dioxide determinations showed a variation from 270 to 430 parts per million, or an average throughout the year of 335 parts per million. No regular variation of the amount of carbon dioxide with the month or location in city could be discovered.

The quantity of carbon dioxide present averages but 35 parts per million higher than that present in the

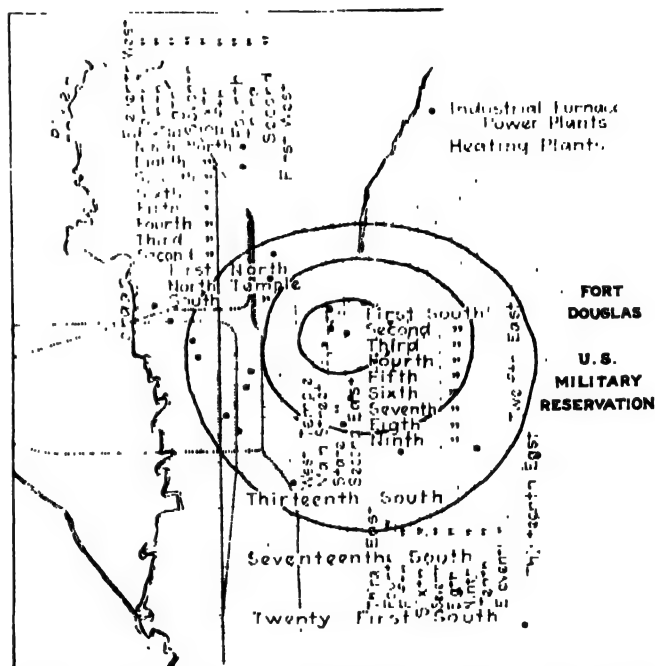

FIG. 6. MAP OF SALT LAKE CITY, SHOWING THE LOCATION OF INDUSTRIAL FURNACES, POWER AND HEATING PLANTS AND ZONES OF SMOKE CONCENTRATION

pure country air. Carbon dioxide is a negligible factor in the pollution of Salt Lake City atmosphere.

Nitrous Acid. Analyses showed a variation in the nitrous acid content of the air of from 0.009 to 0.0322 mg. per cu.m. The amount of nitrites present is higher on smoky days than on clear days.

Chlorine is present in very minute amounts, possibly carried as spray from the Great Salt Lake. Only a few determinations were made. These varied from 0.002 to 0.004 mg. per cu.m.

Sulphur acids are present in amounts less than 0.1 mg. per cu.m.

Ammonia varies from 0.001 to 0.08 mg. per cu.m.

None of these impurities is present in harmful amounts.

(Part II will be published in a subsequent issue.)

Corrosion Prevention in Petroleum Refining Vapor Systems

BY RALPH R. MATHEWS AND PHILIP A. CROSBY

IN A previous article¹ we showed that when petroleum which contained brine, with magnesium chloride as one of its constituents, was distilled in pipe stills, hydrochloric acid was evolved by hydrolysis, and in consequence serious corrosion took place in the fractionating system and in the condensers. Michael Freund² has also shown that such a reaction takes place, his observations being made on a Russian crude oil, and others have noticed corrosion when such oils were refined. As it is desirable to prevent, if possible, the rapid corrosion caused by the hydrochloric acid produced, several different methods have been investigated, and this paper covers some of the results obtained.

At the suggestion of President van der Gracht, of the Roxana Petroleum Corp., anhydrous ammonia was first tried as a neutralizing agent. The ammonia was obtained in drums containing approximately 150 lb. These were connected by means of a 1-in. line with the vapor line, just after the vapor left the stills, and before it reached the first dephlegmator.

At first an attempt was made to use a gas-bubbling bottle containing kerosene, and regulating the flow of the gas by rate of bubbling through the liquid. However, due to the low temperature caused by the expansion of gas as it left the cylinder, the bottles were broken and the oil was also carried over mechanically. In consequence the bubbling device was abandoned and the flow of ammonia required was regulated by examining the water which came to the receiving house from the last dephlegmator in the vapor system. Adjustment was made so that it carried a slight odor of ammonia, or at least was alkaline in reaction. Paper impregnated with phenolphthalein has been found best as an indicator of the character of the water. It was chosen because the color change is quite apparent at night, and regulation at night is as essential as during the day.

This method of regulation is not entirely satisfactory, because at times, due to a slight variation in vapor pressure, the odor comes much stronger than at other times; also, when the drum is getting nearly empty the pressure gets low, and it must be closely watched so that the valve can be opened wider. However, the stillmen have become so adept in handling the regulation that very few samples now come to the laboratory showing an acid reaction.

COMPARISON OF OPERATIONS

In order to ascertain the benefits derived from the use of the ammonia in comparison with using none, an average sample of the water which comes from the top of the eighth dephlegmator was analyzed each day over given periods, to determine the iron content. No steam was being used in the system, and the condensed water came from the brine which was originally present in the crude oil. Comparative determinations of iron, in grams per liter of water, as shown in Tables I and II, illustrate the advantage of using ammonia. "Without Ammonia" was using a crude which contained less salt water than the other, and the difference would really have been greater if the same crude had been used as "With Ammonia."

TABLE I. OPERATION WITHOUT AMMONIA

	Reaction of water was acid			
	Iron Content G. per Liter	Estimated Vol. Water-Liters	Est. Wt. of Iron Lost	
			Kg.	Lb.
1st day	3.65	1,000	3.65	8.1
2nd day	3.88	1,000	3.88	8.6
3rd day	4.55	1,000	4.55	9.8
4th day	4.83	1,000	4.83	10.4
5th day	5.01	1,000	5.01	11.0
6th day	4.85	1,000	4.85	10.5
7th day	7.13	1,000	7.13	15.7
8th day	6.11	1,000	6.11	13.5
9th day	7.87	1,000	7.87	17.3
Average per day			5.18	11.4

TABLE II. OPERATION WITH AMMONIA

	Reaction of water was alkaline			
	Iron Content G. per Liter	Estimated Vol. Water-Liters	Est. Wt. of Iron Lost	
			Kg.	Lb.
1st day	0.03	4,000	0.12	0.3
2nd day	0.02	4,000	0.08	0.2
3rd day	0.77	5,200	0.40	0.8
4th day	1.20	6,400	0.76	1.6
5th day	0.11	7,600	0.83	1.8
6th day	0.04	8,800	0.35	0.7
Average per day			2.18	4.8

At first the average sample sometimes came to the laboratory having an acid reaction, due to difficulties in regulating the flow of ammonia. Over a period of five months these showed an average of 0.75 g. iron per liter water, while the total average, including the days when the water was alkaline, was only 0.35 g. Thus the water should be alkaline all of the time, not only to prevent corrosion by the acid vapors, but also the action on the metal of the ammonium chloride, which is corrosive in an acid system.

SALT INCRUSTATIONS

That the ammonia and hydrochloric acid really react and form ammonium chloride has been proved by analyses of various deposits found in the vapor system. In fact, one line was found almost completely closed with a deposit, the composition of which is shown in the first analysis of Table III. The deposits found were variable,

TABLE III. ANALYSIS OF DEPOSITS

	Per Cent
Moisture	0.67
Oil	1.07
Carbonaceous matter	1.20
NH ₄ Cl	5.38
FeCl ₂ ·4H ₂ O	3.42
Iron oxide (by diff.)	88.26
	100.00
Moisture	1.77
NH ₄ Cl	69.50
FeCl ₂ ·4H ₂ O	25.14
Undet. and iron oxide	3.59
	100.00

as shown in the second analysis of materials found in the vapor system. We have also found small amounts of ammonium chloride in the vapor line leading from the last dephlegmator to the tubular condenser.

About a year after the use of ammonia was begun the vapor pressure was found higher than normal in the vapor system. An investigation showed it might be due to deposition of NH₄Cl. The next to the last dephlegmator was accordingly washed with warm water and approximately the following amounts of material removed:

	Lb.
Ferrous chloride	102
Ammonium chloride	459
Insoluble matter	23

This is further proof of the reaction between the acid and ammonia and shows that the deposited NH₄Cl and FeCl₂ must occasionally be removed. The FeCl₂ and

¹CHEM. & MET. ENG., vol. 22, No. 11, p. 491.
²Chemiker-Zeitung, vol. 43, No. 149, p. 587.

insoluble matter (iron oxide) shows there is still some corrosion even when ammonia is used, but the longer life of the condensers as shown below is clearly indicative of the benefit derived.

DECREASE IN DEPRECIATION

Before using the ammonia the tubular condenser was in use for approximately 100 days before it was necessary to replace any tubes, but after using ammonia it was about 280 days before any tubes had to be replaced. Not only is the cost of the tubes to be considered, but also the necessary labor and inconvenience sometimes caused. Where condensers are not in parallel it would mean shutting down the unit while new tubes were put in.

The cost of installation is small, and the main expense of course is for ammonia. It will probably vary with market conditions, but when using Mid-Continent crude oil it should not be over \$0.005 per bbl. of oil run.

Determination of the water content of the crude oil in each tank before running, and the amount of salt in the oil, have been found of assistance. In connection with determination of the salt content a special method has been developed so that the amount present can be found without the necessity of waiting until sufficient brine separates from the crude. The method has been found very useful on crudes where the brine is present as a semi-permanent emulsion. Also, as stated before, the amount of iron in the water coming from the last dephlegmator is determined each day by analyzing an average sample for twenty-four hours.

USE OF SODA ASH NOT SUCCESSFUL

While the cost of using ammonia is not excessive compared to the benefit derived, it does, of course, mean an added refining expense. With the idea of reducing the cost, an attempt was made to prevent the formation of the hydrochloric acid by the addition of soda ash to the oil itself, the idea being to get the old familiar reaction between the magnesium chloride and soda ash. A solution of approximately 15 deg. Bé. was prepared and at first was put into the suction line of the feed pump, with the idea of getting as thorough mixing as possible. A proportional pump was used in adding the solution so approximately the proper amount could be added. However, the solution froze on contact with the cold oil and caused pump trouble. A connection was then made so that it could be added to the oil after the oil had been through one heat exchanger. The amount of solution added was so small, though, that even with the line covered the solution froze in the line before it reached the warm oil at the heat exchanger.

A 1-in. line inside of a 2-in. steam line was next tried, and while it fed in fairly well, the flow was intermittent and thus was not entirely satisfactory. In addition we found that even when the soda ash was going into the crude the water from the last dephlegmator was still slightly acid. This seemed due to organic acids collected from the vapor by the water and to carbonic acid. Samples of non-condensable gas were collected and analyzed when ammonia was not being used. They were found to contain 10 to 15 per cent CO_2 . As the ammonia effected complete neutralization, it was of course a point in favor of its use. In addition, the use of soda ash apparently increased the amount of salts deposited in the retorts of the pipe still. In view of the above the attempt to use soda ash was finally abandoned and the addition of ammonia was continued.

Experiments which have been lately made show that the aqueous solution of ammonia is cheaper than the anhydrous, and we shall probably be using it exclusively in the near future.

We have not as yet been able to isolate the organic acids referred to above, neither have we been able to locate the source of carbon dioxide which we have found in the vapor system. However, we are proceeding with an investigation as rapidly as routine work will permit.

Wood River, Ill.

Will Sodium Fluoride Come Into General Use for Preserving Wood?

By GEORGE M. HUNT

THE desirability of sodium fluoride as a wood preservative is practically established. The data collected by the Forest Products Laboratory and published in the article by C. H. Teesdale on "Use of Fluorides in Wood Preservation" are strong evidence to this effect. One large coal-mining company has been using sodium fluoride since 1915 for the treatment of its mine timbers, in preference to either coal-tar creosote or zinc chloride. In the 1919 *Proceedings of the American Wood Preservers' Association*, pages 138 to 145, Galen Wood, chemist of the Port Reading creosoting plant, presents evidence of the preservative value of sodium fluoride and the practicability of its use.

In spite of its proved value for the purpose, sodium fluoride is not being used to any extent as a wood preservative except by the single company mentioned. Other companies have expressed an interest in it, but they have never used it in quantity. The reason for this is obvious when the price of sodium fluoride is compared with that of zinc chloride, which is the standard water-soluble wood preservative. At present sodium fluoride is selling at about 15c. per lb., while zinc chloride is purchased in large quantities at approximately 8c. per lb. This difference in price prevents the wide use of sodium fluoride in the wood-preservation industry.

USE OF ZINC CHLORIDE

Some idea as to the field which might be opened to sodium fluoride in this industry may be obtained from Table I, compiled from the 1919 *Proceedings of the*

TABLE I AMOUNT OF ZINC CHLORIDE USED IN THE U. S. AND WOOD TREATED WITH IT FROM 1909 TO 1918

Year	Zinc Chloride Used, Lb.	Amount of Wood Treated Cu Ft
1909	16,215,107	52,678,797
1910	16,802,532	54,804,557
1911	16,359,797	56,814,039
1912	20,751,711	57,803,341
1913	26,466,803	44,772,287
1914	27,212,259	57,352,587
1915	33,269,604	62,849,901
1916	26,746,577	52,075,638
1917	26,444,689	54,311,726
1918	31,101,111	60,385,421

* These figures include wood treated with straight zinc chloride solution; wood treated with mixtures of creosote and zinc chloride.

American Wood Preservers' Association, which gives for a number of years the annual consumption of zinc chloride in preserving wood and the amount of wood treated with it.

Assuming a uniform cost of 8c. per lb., the amount of zinc chloride used in 1918 represented a value of

Wood Preserving, January-March, 1917.

nearly \$2,500,000. At pre-war prices for zinc chloride, the value of this amount would have been in the neighborhood of \$1,250,000.

Of the various forms of timber treated with zinc chloride, nearly 95 per cent is in the form of railroad ties, and most of the remainder is construction timber. Small amounts are occasionally reported as used for poles, piling, wood paving blocks, cross-arms and miscellaneous lumber. Reports of the total amount of timber treated in the United States in 1918, the latest year for which statistics are available, show that nearly one-half was treated with zinc chloride.

Since zinc chloride is soluble in water, it will leach out if the treated wood is used in water or very wet locations. It finds its greatest use, therefore, in the drier parts of the country. In the Southern states coal-tar creosote is used in preference to zinc chloride particularly in treating piling to be used in water.

ADVANTAGES OF SODIUM FLUORIDE

Sodium fluoride can be used in the same manner, with the same apparatus and for the same wood-preserving purposes as zinc chloride. It possesses several minor advantages, but its superiority over zinc chloride for general use is not sufficient to justify the wood preserver in paying a much greater price for it. A comparison of some of the properties of these two chemicals which are of importance from a wood-preserving standpoint is given in Table II.

TABLE II—COMPARISON OF PROPERTIES OF ZINC CHLORIDE AND SODIUM FLUORIDE

	Zinc Chloride	Sodium Fluoride
Solubility in water	Soluble in all proportions	Soluble to about 4 per cent
Toxicity	Extremely toxic when inhaled or taken internally	Over twice as toxic as zinc chloride
Corrosive effect on steel	Slightly corrosive, but not on steel	Much less corrosive than zinc chloride
Effect on paint	Cannot be successfully painted over	Does not injure paint
Convenience of shipping	Shipped in 50 per cent solution or solid, but solid form is delicate and must be sealed in air-tight container	Shipped as dry powder in slack coops
Present cost	About 8¢ per lb.	About 15¢ per lb.

From the fact that the toxicity or poisoning property of the sodium fluoride is given as more than twice that of zinc chloride, it might be argued that it would be twice as effective as a preservative, or that only one-half as much need be injected into the wood to produce the same effect. The toxicity is determined by laboratory tests only. Such test must be backed up by service tests, where timber is treated and put into actual use, before it can be determined positively that the relatively smaller amount of sodium fluoride indicated by the toxicity tests can be safely used. Tests of this kind are under way, but it will be a number of years yet before the results are known.

QUESTION OF RELATIVE PRICE

The extent to which sodium fluoride will be used in treating wood, therefore, will depend mainly upon its price. There is little doubt that large contracts for sodium fluoride would be placed if the purchaser could be assured of a price equal to or less than that of zinc chloride. If sodium fluoride should begin to compete sharply with zinc chloride, the price of the latter would probably fall. Lowering prices of these two preservatives would encourage treatment and result in a larger volume of treated timber.

The question as to whether it is possible to manu-

facture sodium fluoride at a price low enough to compete with zinc chloride was recently answered as follows by a man very familiar with manufacturing conditions: ". . . you must consider that fluor spar which formerly cost about \$10 now costs about \$50, and hardly enough of 'acid quality' is obtainable for this enormous price. Soda ash costs more than twice as much as it formerly cost. Pyrite for the manufacture of sulphuric acid is also much higher than formerly. To this increase in the cost of all material entering into the manufacture of sodium fluoride comes the cost of labor, which has more than doubled in the last years. The cost of construction and repairs is also at least twice what it was formerly. Considering all these factors, the present price of sodium fluoride is very moderate. We are well aware that at present prices sodium fluoride can compete with zinc chloride for special purposes only. This applies to sodium fluoride made from hydrofluoric acid and soda ash."

From this it is evident that there is no apparent possibility of manufacturing sodium fluoride from fluor spar very cheaply under present conditions.

In the manufacture of fertilizer from phosphate rock, it is possible to recover a certain amount of sodium fluoride from the waste gases produced in the process. This is being done in a small way, but it is not a simple process, and a number of plants which have considered it have been deterred from the undertaking because of the chemical difficulties involved, the cost of constructing the required plant, or the difficulty of obtaining labor and materials. This industry offers a possible future source of cheap sodium fluoride; and although at present it is not producing much, it is to be hoped that the time is coming when it will be possible to furnish the wood-preserving industry with an ample supply at an economical price.

The ingenuity of our chemists should make available for general use a material having such desirable wood preserving properties.

New Paper Pulp Industry in Argentina

The first factory in Argentina to make paper pulp was to begin operations during September, reports Trade Commissioner Brady, of Buenos Aires. The mill, which is located near Barranqueras, in the Chaco Territory, on the Parana River, is using as raw products a species of bog grass called "paja brava." This grass grows during the whole year, and is so abundant in the swampy places that it has been considered a nuisance.

At present the mill is equipped to make only pulp in sheets and strawboard for paper boxes. It has a capacity of three tons of strawboard per day. The construction of the mill was begun over two years ago during the war. The owners are German-Argentine and the engineer in charge is an Austrian. The equipment consists of old machinery rebuilt with some machines which were made in the country. It is intended later to increase the equipment in order to manufacture a finer quality of pulp and to obtain a greater production.

There is undoubtedly a good field for a more elaborate wood-pulp mill in the north of Argentina, since an abundance of trees and plants suitable for paper making exist in that region and there is a market for the product in Argentina.

The Fundamentals of the Electrolytic Diaphragm Cell*—III

Relation of Brine Concentration and Temperature to Voltage and Amperage—Cell Lag and Instant Results—Effect of Sulphate of Soda on Carbon Electrodes — Appendix: Calculation of Decomposition Voltage; Theoretical Yields per Ampere-Hour†

By HUGH KELSEA MOORE

AS HAS been previously stated, it is possible to feed to the cells a salt solution of 99 per cent saturation. This does not mean, however, that the saturation in the inside of the cell will be 99 per cent saturation, for this is rarely the case. Most cells running at average decomposition efficiencies decompose the brine faster than it comes in. The average brine saturation in a cell running 93 to 95 per cent current efficiency varies from 80 to 82 per cent. It might be interesting to see what effect the brine saturation has on the voltage of a cell. To show this Table IX is submitted, illustrated by Fig. 9.

TABLE IX. DROP IN VOLTAGE, WITH INCREASING SATURATION

Brine Saturation at 20 Deg. C.	Cell Temp. Deg. C.	Drop in Voltage	Ampere
15	28.0	0.00	1,200
35	27.5	0.06	1,200
50	27.8	0.18	
	28.0	0.24	
	27.8	0.28	
	28.0	0.34	

Lowering the brine concentration in the cell not only uses up power but it tends to make the current electrolyze water, with the resulting liberation of nascent oxygen at the anode with the consequent more rapid

FIG. 9. RELATION OF ANODE BRINE SATURATION TO CELL VOLTAGE. CONSTANT TEMPERATURE

destruction of the carbons. I cannot take the time to go into this now, but will be content with reference to the rapid destruction of the carbons. (See Table VIII, and Fig. 8C.)

EFFECT OF TEMPERATURE ON VOLTAGE AND AMPERAGE

It is often difficult to evaluate the effects of brine concentration because of the disturbing effect of another variable—viz., temperature. To illustrate this I submit Table X and Fig. 10.

The abscissæ are temperatures in degrees C., while the ordinates show the decreases in voltage. Another set of ordinates show the per cent saturation of the brine at the varying temperature. The solid line shows the per cent saturation at 20 deg. C. The dash line corresponds to 640 amp., while the dot and dash line corresponds to 850 amp. It will be noted that these lines are nearly

TABLE X. BRINE TEMPERATURE INCREMENTS AND CELL VOLTAGE DECREMENTS

Brine Temp. Deg. C.	Saturation at 20 Deg. C.	Cell Volts	Decrease in Voltage	Ampere

76.0		3.20		850

parallel, showing in each case approximately the same degree of drop. The solid line is inserted into this chart to show the concentrations in this particular experiment, but as the concentration and temperatures may vary independently of each other, this curve must not be used to predict a concentration at a given temperature.

In order to get the effects of temperature on voltage two experiments were conducted with the object of keeping the concentration constant. Table XI, illustrated by Fig. 11, and Table XII, illustrated by Fig. 12, show the results obtained.

TABLE XI

Brine Temp. Deg. C.	Saturation at 20 Deg. C.	Cell Volts	Decrease in Voltage	Ampere

In each case the abscissa is the brine temperature in the anode compartment while the ordinates represent the decrease in voltage. As before, the solid line represents the concentration of the brine, while the dash line shows the drop in voltage. The saturation in Figs. 11 and 12 has been maintained by adding solid salt. The temperatures were obtained by blowing steam into the cell.

Raising the temperature in a cell also increases the fluidity of the brine and consequently it is well that we should know the effect.

The experiments illustrated by Tables X, XI and XII were conducted on especially high voltage cells in order that the increased flow due to rise in temperature should

*Read before the American Institute of Chemical Engineers, Montreal, June 28, 1920.

In order to illustrate still further the effect of temperature on a diaphragm cell Tables XIV, XV and XVI and Figs. 14, 15 and 16 are submitted, showing the

effects of blowing steam into the cell on the different factors noted. I wish to particularly call your attention to the decrease of chlorate in caustic liquor with the increase in temperature. In all probability this may be accounted for by the increased activity of the nascent hydrogen at the cathode on the decreased stability of sodium chlorate.

CELL LAG AND INSTANT RESULTS

On page 1074 I spoke of the possibility of getting more than theoretical efficiencies on tests of short intervals of time. I mentioned at this time one cause which would make it possible to obtain such results.

In Fig. 14 you will see another illustration of this fact, but for another cause—i.e., the lag in the cell. In the case before you we have a beautiful illustration of this fact. It will be noticed that during the experiment the causticity dropped from 35 to 16, while the flow increased from 7.6 to 18.6. The above condition always

FIG. 13. RELATION OF FLOW FROM CELL TO BRINE TEMPERATURE

gives an apparent efficiency higher than the actual, and as the actual is near 100 per cent the apparent efficiency will be over 100 per cent. There is in every cell a certain volume of caustic held by capillary attraction in various parts of the cathode compartment. Now if one volume of the strong caustic so held is replaced by a light volume of a weaker caustic, the caustic effluent will contain more NaOH than was actually produced during the time in question.

While I am speaking of the high efficiencies of cells I might mention that the same effect will be produced if the cells run at an abnormally high amperage just before a test and then drop to normal as the test commences. I have known some crooks to do the above purposely for a joint test. This causes a high efficiency due

to the lag in the strong caustic getting away. Of course if these conditions are reversed you get efficiencies correspondingly low.

The above considerations are based on cells in which the amperage is accurately determined.

In studying Fig. 16 it will be seen that there is a rise in voltage on the second hour, even though there is a rise in temperature. This is due to a rise in amperage at the same time. The volts continue to rise but it will be noticed that the temperature drops while the amperage remains stationary. It will be noted also that the brine in the anode compartment is only 65 per cent saturation.

EFFECT OF SULPHATE

Many do not realize that small quantities of sodium sulphate in the salt fed to the cell can have a deteriorating effect on the cell itself. Experiments have shown that the absolute removal of sodium sulphate from the brine actually decreases the amount of carbon dioxide in the chlorine gas. The presence of this carbon dioxide in the gas not only causes a loss of brine in making bleach but it indicates a deterioration of the carbons in a cell. The loss from the carbons is, however, much greater than one would suppose from the amount of carbon dioxide in the gas. The explanation is simple. As that carbon going into carbon dioxide is removed from the structure of the carbon the cohesive force of

other particles is lessened and they sluff off by the friction of the circulating electrolyte.

From the above one would expect that the absolute removal of sodium sulphate from the brine would increase the life of the carbons. Actual experiment has proved such to be the case. I am not, however, going to give these figures, inasmuch as I have not tried enough experiments to get an average figure which I can term reasonably correct.

It might be interesting to note the increasing amount of chlorate formed in a cell of the submerged diaphragm type by the addition of a brine containing 1 per cent and 2 per cent sodium sulphate. Fig. 17 shows this. Inasmuch as the lag in the cell is very large and the cell had not reached equilibrium owing to the short time of run, I cannot give you a chart showing the per cent of chlorate which would uniformly be present for different percentages of sodium sulphate. The matter, however, is very important, inasmuch as herein lies a great source of danger to say nothing of expense.

In evaporating a caustic solution it is possible to crystallize out most of the salt but impossible to crystallize out the sodium chlorate. When the kettles containing such chlorate become heated to a sufficient temperature, the sodium chlorate is liable to explode, throwing tons of molten caustic on the floor. Even if the kettles are so run that the sodium chlorate decom-

FIGS. 14 TO 17.

Figs. 14 to 16. Effect of steam on Allen-Moore cell. Fig 17 Effect of Na_2SO_4 solution on Le Sueur cell

poses gradually and smoothly, we may have a low test caustic from the presence of sodium chloride formed by the dissociation of the sodium chlorate.

Appendix

CALCULATION OF DECOMPOSITION VOLTAGE

It was stated by Helmholtz in 1847 and W. Thompson in 1851 that in a galvanic element chemical energy is completely transformed to electrical energy. Then if the heat of reaction in calories per gram-equivalent is called U , the electromotive force in volts which could be produced by it E ,

$$E = \frac{U}{23046} \quad (1)$$

This is often approximately true, its error depending on the temperature coefficient of the electromotive force, and this in turn on the difference of the molecular heats of the reacting substances and the resultant substances. The theoretical basis of the correct method was established by Gibbs and Helmholtz somewhat later, but the new equations were of little use until Nernst's heat theorem was applied to the problem. The result may be written in the form:

$$E = \frac{U}{23046} - \frac{2BT^2}{23046} \quad (\text{approx.}) \quad (2)$$

Where T is the absolute temperature, in Centigrade degrees, and $B = \frac{1}{2T}$ (specific heat of all the reactants per gram equivalent) - (specific heat of all the resultants per gram equivalent). But to apply even this expression, calculations must be made on a basis, first, of each phase being a pure solid or liquid substance; not, for instance, a solution. In the case of the ordinary electrolytic chlorine cell, for instance, the required specific heats must be known at a temperature at which

the hydrogen and chlorine are liquid, and the salt and caustic are solid NaCl.2H₂O and NaOH.7H₂O respectively. The requisite correction to bring up the results to room temperature can then be made on the basis of the solubility-temperature curves. Such data, however, and especially the specific heats of low temperatures, are known for only a few substances. It is evident, then, that with the physical data now obtainable, the accurate calculation of decomposition potentials is impossible.

The approximate voltage obtained by equation 1 is, in fact, commonly used in practice. The unknown correction factor may be either positive or negative, and may range from zero to three-tenths, or four-tenths of a volt, or even more. In the case of the chlorine cell it is supposed to be about -0.1 volt.

The heat effects and approximate decomposition volt-

British Power-Alcohol Research

It is reported that detailed research is shortly to be undertaken in India with a view to determining the practicability of producing power alcohol on a commercial basis, reports A. M. Walker, clerk to American Trade Commissioner, London.

At the same time that these experiments are being conducted, efforts are being made in Great Britain to make possible the ready use of such a substitute fuel whenever it becomes available in sufficient quantities. With this object in view, the Empire Motor Fuels Committee of the Imperial Motor Transport Council has recently appointed small technical committees to consider specifically:

(1) The modification of customs and excise regulations pertaining to alcohol;

(2) Experiments for determining the best conditions for developing the alcohol engine and types of alcohol fuels, alone or in mixture, for industrial purposes; and

(3) The denaturing of alcohol.

The problem of ascertaining what is a suitable denaturant is regarded as of very great importance, and the Empire Motor Fuels Committee, 50 Pall Mall, London, S. W., 1, has invited in confidence interested members of the public to submit practical suggestions as to possible denaturants. Such proposals will remain the sole property of the individual who furnishes them, and his interests will be properly safeguarded. The special requirements of a satisfactory denaturant, according to the committee, are (1) deterrent taste and smell; (2) non-poisonous; (3) must not be removable at a commercial cost; (4) must be readily detectable in small quantities; (5) must be readily mixable with the spirit, and (6) must be inexpensive.

Legal Notes

BY WELLINGTON GUSTIN

Fertilizer Manufacturers Should Watch Their Sales Contracts

In a suit by the Montezuma Fertilizer Co. against B. C. Hodges, the action resulted from a purchase by Hodges of certain fertilizers under a special formula furnished by the buyer, whereby it was agreed that the nitrogen was to be derived from "equal parts of fish scrap, blood and tankage." This fertilizer was shipped out under the registered brand "840." This brand "840" as registered with the Commissioner of Agriculture of Georgia is there stated to derive its nitrogen from "blood, tankage, cyanamide and sulphate of ammonia." A properly certified copy of the official analysis of this fertilizer "840" as made by the state chemist and furnished to the purchaser showed a deficiency in the phosphoric acid, which resulted in a lessening of the commercial value of the fertilizer amounting to more than 3 per cent. Subsequently, upon the request of the seller, the Department of Agriculture, through the state chemist, rechecked the original analysis from the original samples, and certified the new and corrected analysis, which showed a lessening of the commercial value amounting to less than 3 per cent. The state chemist testified that the corrected analysis was true and correct.

DEFENDANT CHARGED FERTILIZER WAS NOT AS REGISTERED

Upon a suit for the purchase price of the fertilizers sold Hodges set up two grounds of defense: (1) That brand "840," under which name or number the fertilizer was furnished, as registered with the Georgia State Commissioner of Agriculture, stated that its nitrogen was derived from "blood, tankage, cyanamide and sulphate of ammonia," whereas the fertilizer as actually shipped and sued for derived its nitrogen from "equal parts of fish scrap, blood, and tankage," and therefore the sale was illegal and the contract of sale void, inasmuch as the registration laws of Georgia governing fertilizers had not been complied with; (2) that in event the contract should not be adjudged illegal and void, he was still entitled to a reduction of 25 per cent of the price as a penalty, because the official analysis showed that the actual commercial value of the fertilizer fell more than 3 per cent below the guaranty.

Upon trial the Judge held the contract sued on was not void under the first contention given above. He further held the second or corrected analysis to be inadmissible in evidence for the reason the Georgia statute did not provide for any such corrections to be made of an official analysis. Therefore he applied the 25 per cent penalty and gave judgment accordingly.

Appeal by both parties was had and the Court of Appeals of Georgia certified certain questions to the Georgia Supreme Court. In answering the questions the court said that "where a contract for the purchase of fertilizers specifically provides from what source the phosphoric acid, the nitrogen or the potash is to be derived, and where the fertilizers furnished in accord-

ance with such special order, such contract of sale would be void unless the fertilizers so furnished had been registered as provided by Civil Code 1910, Section 1771.

"The fact such fertilizers were furnished as ordered under a name or brand properly registered with the Commissioner of Agriculture, but which registration gives a source other than the actual one from which the phosphoric acid, nitrogen or potash is derived, would not operate to change the rule above stated."

COURT DECIDES THERE WAS A VARIANCE

And where the brand as registered states that the nitrogen is derived from "blood, tankage, cyanamide and sulphate of ammonia," and the proof shows that in accordance with the contract of purchase the nitrogen is derived from "equal parts of fish scrap, blood and tankage," there is such a variance between the registered sources and the actual sources as would invalidate the contract of purchase, under the statute governing registration of fertilizer brands.

On the question of whether a corrected analysis from the same sample of fertilizer may be made, the court said that after a sample of fertilizer drawn by the official inspector has been filed with the Commissioner of Agriculture and has been analyzed by the state chemist and certified to said Commissioner and by him recorded and entered as official, the State Commissioner of Agriculture has the right and power to make, through the state chemist, another or corrected analysis from the same sample, which upon proper certification is admissible as evidence in the courts of Georgia in the trial of any issue involving the merits of said fertilizers.

Strike Provision in Sales Contract

The principles laid down in the decision of the United States Circuit Court of Appeals, Fourth Circuit, delivered in the case of the Acme Manufacturing Co. against the Arminius Chemical Co. have to do with a strike provision in a sales contract. The case has been up again before the court on a rehearing, but there was no change in the opinion.

The chemical company contracted to sell sulphur pyrites to the Acme company during 1916, the contract being "subject to delays and stoppages caused by strikes, accidents, delays by railway companies, and causes beyond the selling company's control."

The chemical company made similar contracts with others, and its entire obligations for deliveries in 1916 amounted to 64,793 tons. In January of that year, after these contracts were made, a cave-in occurred in the mine which prevented delivery of all but 8,977 tons of pyrite, the Acme company receiving but 796 tons under its contract calling for 6,000 tons.

The Acme company contended that an accident, strike or suspension clause in a contract, under circumstances analogous to the present case, does not justify the abrogation of such contract, but does have the effect of suspending performance only, except in cases where such accident or strike renders it impossible of ever being performed. In addition to this the court pointed out that certain letters, passing between the parties relating to postponement of shipments to the year 1917, along with a part performance of the contract by the chemical company, established a contract for shipments during 1917. It was said that even if the provisions of the contract had been such that, under the circum-

stances of this case, it would have expired on Jan. 1, 1917, as the contract provides, the same was extended by the agreement of the chemical company as shown by its letters.

Holding that the buyer is entitled to sue in anticipating a breach, the court said that where, during performance by the seller of a contract to deliver to the buyer a stated quantity of sulphur pyrites in monthly shipments, it expressly repudiated the contract on the ground that it had expired and refused to make further shipments, the buyer had the right at its option to treat the contract as ended and to maintain an action for its breach.

In stating the measure of damages for breach it was said that where the seller repudiated its contract without justification after partial performance, and where the buyer used diligence, but was unable to buy elsewhere under the market price, his measure of damages was the difference between the contract price and the market price at the time and place of delivery.

STRIKE PROVISION DOES NOT EXCUSE NON-DELIVERY

On the question of the strike provision in the contract the court laid down the rule that such a strike provision does not excuse non-delivery within a reasonable time after the strike has ended. It was contended that "an accident, strike or suspension clause in a contract has the effect of suspending performance only, and never justifies the abrogation of the contract and the refusal to ever perform it, unless such strike, accident, etc., makes the contract impossible of ever being performed."

In passing upon the point the court in another case, *Jackson Phosphate Co. vs. Carleigh Phosphate, etc., Works*, 213 Fed., 743, said: ". . . this court held that where one charges himself with an obligation possible to be performed he must make it good, and that unforeseen difficulties, however great, will not excuse him. It was also stated by the court that the rule as announced was subject to the qualification that, where a contract contains a limitation upon an otherwise absolute undertaking, one will be relieved from such obligation 'to the extent that such conditions rendered it unable to perform the contract fully, and to this extent only.'"

The rule as announced in 35 Cyc., 249, was adopted by the court. This statement follows:

"Where the contract provides that delivery shall be subject to strike, the existence of a strike merely suspends deliveries during the strike, and does not terminate the contract, and the seller is therefore bound to resume deliveries after a reasonable time after the strike has ceased.' Indeed the rule is so well established that we do not deem it necessary to cite further authorities.

"A careful consideration of the authorities relied upon by the defendant leads us to the conclusion that they do not apply to the case at bar. As we have stated, under this provision of the contract the defendant could have required the plaintiff to make the balance of the shipments within a reasonable time, and, such being the case, we think that such provision likewise inures to the benefit of the plaintiff, and that therefore the plaintiff was entitled to deliver the rock within a reasonable length of time after cars were to be had, and that the effort of the defendant to cancel the contract and its refusal to accept further deliveries under the same

entitled the plaintiff to recover the amount sued for in this action."

The court said this rule was now well established in law.

PRO RATA DELIVERIES ON CONTRACTS

Again in the instant case the Acme company contended that the chemical company could not avail itself of the defense of pro rata deliveries on its several contracts. The court said the defendant is entitled to such defense where it finds it impossible, from causes over which it has no control, to fulfill the contract. In such cases defendant is required to do the next best thing, to wit, to apportion the amount available among all its customers, giving to each one his ratable share. This is an exception to the general rule, and is applied only for the relief of an unfortunate defendant who has, by this conduct, shown that he has in good faith made an honest effort to carry out the provisions of his contract. In order to enable one to avail himself of this defense, says the court, it must appear that he has treated all customers with absolute fairness, and it must further appear that in the circumstances he had done all that could be expected from one whose purpose is but fair dealing, giving each of his customers the ratable share to which he is entitled under the contract.

But the court pointed out that of the 13,848 tons of pyrites delivered on its 1916 orders, 11,110 tons were delivered to Caraleigh Phosphate Co., Grasselli Chemical Co. and the Richmond Guano Co., and these three favored customers were the only ones with whom the defendant had made new contracts. In view of these facts the court held that the seller could not escape liability on the principle of pro rata deliveries.

The judgment below was reversed and a new trial granted.

Claim of Noxious Ammonia and Insufficient Content Not Allowed by Court

In the action by the Palmetto Guano Corporation against J. D. McCormick to collect on a note given for the purchase price of thirty-two tons of commercial fertilizer, the defendant alleged in defense of non-payment that the ammonia content of the fertilizer was only 2.7 per cent when the contract was for a 3 per cent ammonia, and that the ammonia present was noxious because it was derived from a leather product. The trial court directed a verdict for the company and the Supreme Court of South Carolina has affirmed this judgment.

Defendant offered the testimony of an expert witness named Rice to prove that 1 lb. of the fertilizer sent to the witness by McCormick contained only 2.7 per cent of ammonia, that the fertilizer contained a leather product and that the ammonia was probably derived from a leather product. It appears McCormick's whole reliance to defeat a recovery was on the competency of the testimony of Rice to prove a deficiency of ammonia and the noxious character of it.

The Supreme Court pointed out that there was no testimony to show that the 1 lb. analyzed by the witness Rice was taken out of the fertilizer sold by the company to the defendant. And it said had the testimony been admitted it would have tended to show only that out of thirty-two tons of fertilizer 1 lb. of it fell short of the ammonia contracted for by only an inconsiderable amount, and it does not show that the ammonia present was noxious.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Process for Coking "Non-Coking" Coals.—After a thorough study of coke-oven phenomena, ARTHUR ROBERTS, of Evanston, Ill., offers the following explanation of the difference between coking and non-coking coals. From this theory he has developed a process for coking coals which have been found unsuitable for the manufacture of metallurgical coke in the ordinary type of coke-oven.

In general coke is formed by binding the fixed carbon and ash constituents of the coal together by means of a cementing material which is made out of and from the resinoid volatile hydrocarbon contained in the original coal. The classification of coals as "coking" or "non-coking" has been based upon results obtained in existing types of ovens. Semi-bituminous coals have been found to yield metallurgical coke, whereas the larger percentage of bituminous coals have failed in this respect. In the so-called "coking" coals, the amount of resinoids naturally present is so large that a sufficient proportion of binding material will be formed almost without regard to the process or manner of application of heat treatment, whereas in the so-called "non-coking" coals, the proportion of resinoids is so small that special consideration must be given to a process producing the heat treatment necessary to increase the production of and conserve the binding material from the resinoids. The binding material must be formed at the right time and under the proper conditions, if coke is to be produced. Opposing these conditions are the tendency for the resinoids to vaporize and escape from the coking mass, and the tendency toward destruction of the resinoids by chemical combinations with other elements present, particularly with oxygen. The influence of the oxygen content and of the hydrogen: oxygen ratio on the classification of coals is clearly shown from typical analyses. Coking coals have less than 10 per cent oxygen and a hydrogen: oxygen ratio (on the dry basis) of more than 0.58. That the hydrogen: oxygen ratio or its reciprocal is a function of the geological age of the coal is shown from the following data:

	Oxygen: Hydrogen Ratio
Wood	6.82
Peat	5.65
Lignite	5.06
Sub-bituminous coal	3.46
Bituminous coal	3.09
Semi-bituminous "coking" coal	1.11
Anthracite	0.61

The disturbing factors referred to are negligible in the case of most "coking" coals on account of the high content of resinoids and the low oxygen: hydrogen ratio, but they exert a controlling influence in the case of "non-coking" coals.

It is evident from a study of heat exchange in a coke-oven that the zone of volatilization of the resinoid materials advances from the sides of the oven toward the center as heat is transferred from the hot walls to the charge and that this zone precedes the formation of coke or what may be termed the coking wave. In

treating non-coking coals, the conversion into coke will not occur unless the crest of the coking wave reaches each point in its travel rapidly enough to catch the resinous materials and convert them into cementing material by decomposition before these resinous materials can be oxidized or vaporized. The front of the wave must be steep enough to bring about this conversion, otherwise when the crest of the wave arrives the materials will have been removed from the mass. This involves supplying an amount of heat sufficient to raise the temperature of the whole charge quickly to the most favorable coking temperature. In order to accomplish this the inventor proposes to use a narrower retort and to charge the coal into a heated retort the oven structure of which is so proportioned as to contain an amount of heat sufficient to raise the charge rapidly to 600 to 700 deg. C. The amount of this reserve of heat is partially measured by a comparison of the weight of the walls and hot structure with the weight of the coal, taking account of the specific heat of the walls and structure. In practice, the following proportions have been found to give the best results: Width of retort, 12 to 16 in.; 29 to 30 lb. coal in retort per sq.ft. of heating surface; 12 to 13 lb. coal in retort per sq.ft. of surface in the heating gas passages; approximately 3.8 lb. of wall and wall structure (arranged to give up its heat rapidly on demand) per lb. of coal in the retort. (1,352,696; assigned to American Coke & Chemical Co.; Sept. 14, 1920.)

Anthraquinone by Catalytic Oxidation.—Anthracene in the vapor phase is oxidized by oxygen in the presence of an oxide of vanadium as a catalyzer at a temperature of about 300 to 500 deg. C. (1,355,098; JOHN M. WEISS of New York and CHARLES R. DOWNS of Cliffside, N. J., assignors to The Barrett Co.; Oct. 5, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Acridine Dyes.—Acridine dyes are obtained by heating a mono- or di-formyl derivative of a *m*-diamine of the benzene series with a salt of a monoalkylated or unsymmetrically dialkylated *m*-diamine of the benzene series or with β -naphthylamine hydrochloride, or by heating formyl derivatives of monoalkylated or unsymmetrically dialkylated *m*-diamines of the benzene series or formyl- β -naphthylamine with salts of *m*-diamines of the benzene series or their monoalkylated or unsymmetrically dialkylated derivatives. According to examples, products are obtained from the following pairs of components: 4-formylamino-2-aminotoluene and 3-aminodimethylaniline hydrochloride; 4-formylamino-2-aminotoluene and 4-amino-2-dimethylaminotoluene hydrochloride; diformyl-*m*-toluenediamine and 3-aminodimethylaniline; 4-formylamino-2-aminotoluene and 4-amino-2-methylaminotoluene; monoformyl-*m*-phenylenediamine and 4-amino-2-ethylaminotoluene; diformyl-*m*-phenylenediamine and 4-amino-2-ethylaminotoluene; 4-chlor-1-amino-3-formylaminobenzene and 3-aminodimethylaniline hydrochloride; 4-formylamino-2-aminotoluene and β -naphthylamine hydrochloride; monoformyl-*m*-phenylenediamine and β -naphthylamine hydrochloride; 4-formylamino-2-dimethylaminotoluene and *m*-toluenediamine hydrochloride; 4-formylamino-2-dimethylaminotoluene and 4-amino-2-ethylaminotoluene hydrochloride; formyl- β -naphthylamine and *m*-toluene-

diamine hydrochloride; formyl- β -naphthylamine and 3-aminodimethylaniline hydrochloride; formyl- β -naphthylamine and 4-amino-2-methylaminotoluene hydrochloride. The sulphates, etc., of the diamines may be used instead of the hydrochlorides. The products dye leather yellow to orange red shades. (Br. Pat. 145,802—1919. AKT. GES. FÜR ANILIN-FABRIKATION, Treptow, Berlin, Sept. 1, 1920.)

Purifying Mineral Oils.—A natural or an uncracked oil is desulphurized by vaporizing it and bringing the vapor into contact with granular alumina or ignited magnesite at a temperature below the boiling point of sulphur. The alumina may be prepared from the trihydrate or bauxite. Sulphuretted hydrogen resulting from the dissociation of the sulphur compounds may be absorbed in oxide of iron, Weldon mud, or the like. (Br. Pat. 145,818—1919. J. J. HOOD, London, Sept. 1, 1920.)

Concentrating Ores.—Copper sulphide such as chalcopyrite, carbonaceous material such as graphite or coal, and molybdenite, or any two or more of these substances are separated from other floatable minerals such as sulphides of iron, lead and zinc by an application of the froth-floatation process in the presence of a soluble frothing agent and a small proportion of an alkali, preferably an alkaline silicate. (Br. Pat. 145,852—1919. L. A. WOOD, and MINERALS SEPARATION, LTD., London, Sept. 8, 1920.)

Cellulose Esters.—For the manufacture of cellulose esters of fatty acids, a cellulose is employed which has been preliminarily treated at a temperature not exceeding 30 deg. C. with small quantities of acetic anhydride in presence of a catalyst diluted with glacial acetic acid. Thus, 100 parts of cellulose are treated with 50 parts of acetic anhydride, 3 to 5 parts of sulphuric acid, and 60 parts of glacial acetic acid at a temperature of 25 to 30 deg. C. for three to four hours; 250 parts of acetic anhydride are then added and the mixture maintained at 40 deg. C. for one to two hours to effect esterification. The esters may be separated by precipitation with water, or they may be converted by partial saponification into esters having different solubilities; the precipitated esters are insoluble in chloroform, whereas some of the saponified esters are insoluble in chloroform and soluble in acetone and others soluble in ethyl acetate. (Br. Pat. 146,092—1919. SOC. CHIMIQUE DES USINES DU RHONE, Paris, Sept. 8, 1920.)

Nitrogenous Phosphoric Fertilizer.—A solid nitrogenous phosphoric product suitable as a fertilizer is obtained by converting tricalcium phosphate by heating it with at least an equal quantity of nitric acid, preferably of 50 to 60 per cent strength, into monocalcium phosphate and calcium nitrate, and adding to the thin paste obtained sufficient limestone or other calcium compound or phosphate to neutralize the free acid, and convert the monocalcium phosphate into monohydrogen calcium phosphate. The product obtained is allowed to solidify and is then pulverized. (Br. Pat. 146,097—1919. NITRUM AKT. GES., Zurich, and H. SCHELLENBERG, Personico, both in Switzerland, Sept. 8, 1920.)

Preparation of Methane.—Methane is prepared catalytically by passing a mixture of carbon monoxide and excess of hydrogen through a series of furnaces containing heated contact material, for example, pumice carrying active nickel, the composition of the gases being adjusted at each passage, as for example by the

addition of carbon monoxide, so that the amount of the latter does not exceed about one-fifth by volume of the hydrogen present, and the gases being freed from water vapor after each passage through a furnace. Thus, between each pair of furnaces there is provided a condenser, and a connection with a suitable measuring device for introducing a measured quantity of carbon monoxide, the gases used containing originally a large excess of hydrogen. In place of hydrogen, purified illuminating gas may be employed; and for carbon monoxide may be substituted a purified water gas. The traces of hydrogen finally remaining in the gases may be removed by passage over cupric oxide, or the methane may be liquefied by cooling the gases. (Br. Pat. 146,110—1919. FARBERWERKE VORM. MEISTER LUCIUS & BRUNING, Hochst-on-Main, Germany, Sept. 8, 1920. See also Br. Pat. 146,114—1919.)

Production of Calcium Aluminate.—Calcium aluminate is produced by heating coarsely crushed bauxite and limestone at a temperature such as not to cause fritting, for instance in a rotary furnace, and then fusing the mixture in a second furnace. The fused product may be granulated in water. The first heating may be effected by gases from the second furnace. Alternatively, a blast furnace may be employed, the charge consisting of alternate layers of red bauxite (which may contain 32 to 35 per cent of ferric oxide) mixed with limestone and of coke. The aluminate is recovered as a liquid slag and the iron as pig iron. In another modification, a converter is employed. It is charged with pellets of a mixture of bauxite, limestone and coke dust upon a bed of kindled coke. An agglomerated mass of crude aluminate is obtained, which is discharged by tilting the converter. (Br. Pat. 146,133—1919. SOC. ELECTRO-METALLURGIQUE FRANÇAISE, Paris, Sept. 8, 1920.)

Cementation.—Iron and steel are carburized by the action of nascent carbon monoxide under pressure slightly in excess of that of the atmosphere. The metal is packed in a closed chamber, together with a mixture of powdered charcoal and iron and manganese oxides, and heated. The treatment may be repeated at a higher temperature, say approaching 1,200 deg. C. Any low-grade ore which liberates oxygen at a high temperature may be used, or air or oxygen may be supplied. (Br. Pat. 146,504—1919. T. TASHIRO, Tokyo, Sept. 15, 1920.)

Ammonium Sulphate.—A mixture is made of niter cake, sodium sulphate, ammonium sulphate and water under such conditions that a quantity of anhydrous sodium sulphate is separated, and after the removal of this sodium sulphate, the liquor is used for absorbing ammonia from gases. When used for treating Mond gas, the solution is diluted before the absorption of ammonia and then concentrated again. When treating coke-oven gas or coal distillation gas, this dilution and evaporation may be unnecessary. The absorption of ammonia with the subsequent evaporation causes the separation of sodium-ammonium sulphate, which is removed, and a further evaporation causes the separation of ammonium sulphate, the double salt being used with more niter cake for repeating the process. When dilution and evaporation are not employed, the absorption of ammonia causes the separation of ammonium sulphate, the mother liquor being used with more niter cake for repeating the process. (Br. Pat. 146,546—1919. C. W. BAILEY, H. S. DENNY and W. H. H. NORRIS, all of Langwith, Nottingham, and Sir H. E. F. GOOLD-ADAMS, Westminster, Sept. 15, 1920.)

Purifying Sulphuric Acid.—Sulphuric acid of strength up to about 150 deg. Tw. is freed from arsenic by treatment with sulphuretted hydrogen under such conditions that the acid itself is not attacked—that is to say, the acid is thoroughly impregnated with the gas, which may be effected in apparatus described in Specification 2,113—1909 at a temperature not above about 18 deg. C. and the precipitate is quickly separated, preferably in a vacuum or pressure filter. (Br. Pat. 146,598—1919. G. K. DAVIS, London, Sept. 15, 1920.)

Fumaric Acid.—Fumaric acid is obtained by fermenting sugars (cane-sugar, dextrose, maltose, etc.) by means of a particular species of *Aspergillus* termed *Aspergillus fumaricus*; a description of this mold is given. The fermentation is effected in the presence of chalk or other neutralizing agents; the resulting calcium fumarate is converted into the free acid by means of sulphuric acid, or is converted into lead fumarate, which is then decomposed by sulphuretted hydrogen. (Br. Pat. 146,411—1919. C. WEHMER, Hanover, Germany, Sept. 15, 1920.)

Synthetic Tanning Agents.—Tanning agents are prepared by sulphonating crude anthracene, crude carbazole or anthracene waste, and decolorizing the sulphonated product by means of chlorine, hypochlorites, oxalic acid, formaldehyde, etc.; the decolorized product is capable of giving a light-colored leather. A similar product is obtained by sulphonating the crude bodies specified above by means of chlorosulphonic acid, preferably in the presence of an inert diluent, such as nitrobenzene, at a moderate temperature; this product may be subsequently treated with decolorizing agents as above described. (Br. Pat. 146,427 1919. BADISCHE ANILIN- UND SODA-FABRIK, Ludwigshafen-on-Rhine, Sept. 15, 1920.)

Obtaining Fats From Sulphite Lyes.—The sugar contents of waste sulphite lyes are converted into fat by growing a fungus *Endomyces vernalis* on the lye. The lye is first treated—for example, by aëration and neutralization—and is then inoculated with the fungus whose early growth may be assisted by adding nitrogenous substances such as beet juice to the waste liquor or by first growing the fungus in a culture-medium rich in nitrogen and then transferring it to the lye. The first stage of the process is marked by a large absorption of nitrogen and by rapid growth of the fungus. During the second stage the sugar in the lye is assimilated and converted into fat, and the growth of the fungus is slight. The masses of fungi are finally removed from the solution and treated for the recovery of fat. (Br. Pat. 146,430—1919. W. JEROCH and REICHAUSSCHUSS FÜR PFLANZLICHE UND TIERISCHE ÖLE UND FETTE GES., Berlin, Sept. 15, 1920.)

Fats.—Fats are produced from nutrient media which contain carbohydrates, nitrogenous substances and salts by growing in the media micro-organisms such as aerobic mold-fungi, mildews and yeasts—e.g., *Oidium*, *Sachsia* or *Endomyces* species. The fungi are grown on substrata saturated with the nutrient solution or in the solution itself which is aërated. Injury to the organisms by acids formed during the reaction is prevented by neutralization. As soon as the "vegetation" period is completed the fungi are subjected to a "fasting cure" and the fat formed is extracted in the usual manner—e.g., by pressure or by solvents. (Br. Pat. 146,431—1919. REICHAUSSCHUSS FÜR PFLANZISCHE

UND TIERISCHE ÖLE UND FETTE GES., Berlin, Sept. 15, 1920.)

Saccharifying Cellulose.—Soluble carbohydrates obtained from materials containing cellulose by treatment with concentrated sulphuric or hydrochloric acid, are, after lixiviation in a counter-current, separated from the conversion acids by a diffusion process similar to the "molasses osmose" process. Sufficient acid is allowed to remain with the carbohydrates for complete hydrolysis during subsequent heating, or the acid may be removed as fully as possible, and the solution neutralized, evaporated to dryness and used as fodder. (Br. Pat. 146,455—1919. A. WOHL, Danzig, Sept. 15, 1920.)

Treating Waste Gases From Coke Ovens.—To separate into their constituents the waste gases from coke ovens which remain after the recovery of the tar, benzene, ammonia, etc., the gases are first highly compressed and treated for the removal of water and carbonic acid, then compressed further if necessary and cooled to liquefy all the remaining constituents except hydrogen, and the condensate fractionated to obtain nitrogen, carbon monoxide, methane and ethylene. Alternatively, the gases may be compressed and washed with water or other absorbent for the removal of carbonic acid and then with a solution of common salt or with alcohol or acetone for the recovery of ethylene, and afterward dried and liquefied as before. The absorption liquid may be selected so as to absorb two different gases, for instance ethylene and carbon dioxide, which is convenient if these gases are subsequently to be brought to mutual reaction. The gases given off during the different stages of the coking process may be collected separately and treated according to their composition, and it is more economical to replace the waste gases used for heating the ovens by other gases, such as producer gas, water gas or furnace gas. (Br. Pat. 146,839 1919; ROMBACHER HÜTTENWERKE, Coblenz, Germany, Sept. 22, 1920.)

Crucibles for Melting Aluminum.—Crucibles of graphite, iron or steel, or clay, for use in melting aluminum and aluminum alloys, are provided internally with a coating of aluminum bronze varnish before each melting operation, from which coating the varnish is burned out by heating slowly to about 400 deg. C. The aluminum coating becomes oxidized during the melting operation. The lid of the crucible may have its interior similarly treated. (Br. Pat. 146,841—1919; METALLINDUSTRIE SCHIELE & BRUCHSALER, Hornberg, Schwarzwald, Germany, Sept. 22, 1920.)

Preparation of Pure Starch From Rice. To prepare pure starch from rice without the aid of caustic alkali or common salt, the rice is first steeped for a few hours in cold or lukewarm water until sufficiently softened; the steeped rice is subjected to wet grinding until 98 per cent of the grist passes through a silk having a mesh of 130 \times 130, water being added during the grinding so as to form a paste or cream containing about 38 to 40 per cent of dry solids; and finally the ground mass is diluted with water to a density of 18 to 25 deg. Tw. and the starch separated centrifugally, or to a density of 1.5 to 2 deg. Tw. if separation by decantation is employed. The residue, which is rich in albuminoids, forms a cattle food. (Br. Pat. 147,255—1919; RECKETT & SONS and C. H. HARDY, Hull, Yorkshire, Sept. 29, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Shows Gas to Be an Important Weapon

That military gases played a very important part during the World War is shown by the report just made to Congress by the Surgeon General of the Army. It shows that approximately one man out of three that entered the hospitals of the American Expeditionary Forces was gassed. Enemy gas caused 72,056 casualties, of which 1,271 died. Thus one man out of fifty-seven lost his life. On the other hand, there were 160,783 casualties from battle causes other than gas. From those casualties one out of thirteen died. This does not include the 34,249 men who were killed outright on the battlefield. If they were included, the deaths would be approximately one to three wounded.

Based on the average total strength of officers and men in the American Expeditionary Forces, the number of men gassed was 67.5 per thousand. Of those wounded by rifle and machine gun bullets there were 19.5 per thousand. Wounds from high explosive shells number 16.7 per thousand. The shrapnel wounds were 32.3 per thousand, and wounded by bayonet 0.22 per thousand.

It is pointed out that the ratio of gas casualties undoubtedly would have been greater had the Germans been able to muster large supplies for use during the Meuse-Argonne offensive.

Gas, according to the Surgeon-General's report, accounts for 18 per cent of the time lost by casualties in the hospitals. Of those who were gassed and recovered, less than three per thousand were discharged on account of disability.

Spring Meeting, American Electrochemical Society

Plans have already been made for the spring meeting of the American Electrochemical Society, which is to be held at the Hotel Chalfonte, Atlantic City, April 21 to 23, 1921. A special symposium on corrosion will occupy the morning and afternoon programs of one day and will bring our information on this subject up to date. For another session it is planned to hold a symposium on electrolytic production of organic chemicals. Social features of the meeting will include a smoker and lecture on one evening and some moving pictures of appropriate electrochemical subjects, followed by a dance, on another evening. Dr. Carl Hering, Philadelphia, is chairman of the committee on arrangements.

Secure C.W.S. Commissions

The following have been found eligible to receive commissions as First Lieutenants in the Chemical Warfare Service: John H. Becque, Plasterco, Va.; Crawford M. Kellogg, Salt Lake City; C. E. Palmer, Newark, N. J.; E. G. Steis, South Bend, Ind.; F. J. Swanson, Fort Worth, Tex.; A. H. Waitt, Medford, Mass.

R. Carson Smith of Akron, Ohio, and Hugh A. Stewart of Brooklyn, N. Y., were found eligible as Second Lieutenants.

Chicago Section, American Ceramic Society

The annual meeting of the Chicago Section of the American Ceramic Society was held at the City Club on the afternoon of Nov. 27. The business session was called directly after the luncheon and the following officers were elected for the coming year: B. S. Radcliff, chairman; F. L. Steinhoff, vice-chairman; W. W. Wilkins, secretary-treasurer; C. W. Parmelee, councillor; H. E. Davis, chairman program committee; E. A. Brockman, chairman membership committee.

C. G. Armstrong delivered a paper on "Porcelain Enameling Furnaces." He traced the art of enameling from the time of Rameses III, about 1300 B.C., to the practice of modern times. The enameling of iron in the United States began with the establishment of a plant in Connecticut in 1863. Present-day furnaces may be classified under two groups as to the muffle type—namely, the semi-muffle and full muffle type—and several classes as to method of firing, as coal-fired, producer-fired, semi-producer, recuperative, oil-fired and gas-fired.

Comparisons were made between these types and the new design worked out by the author in which carborundum refractories embodying the regenerative features showed high efficiency for the latter. The paper will be printed in full in a later issue of *CHEMICAL & METALLURGICAL ENGINEERING*.

W. W. Wilkins, of the International Harvester Co., reviewed some notes on "Spark Plug Porcelain," presenting data to prove that 75 per cent of failures of spark plugs used in internal combustion engines of all types are due to faulty mechanical design, leaving only 25 per cent of failures attributable to failure of the refractory material. Tests have shown that zirconium refractories give remarkable performance.

R. Rodehouse described his oil-gas furnace for burning enameled ware. The burners operate with any sort of heavy oil atomized and mixed with air and steam. The control of temperature is absolute, with fool-proof devices to operate. The furnace has no muffles, employs no special shapes in construction, and has remarkably long life.

Oil consumption was said to be under 12 gal. of fuel per hour.

No Official Action by Electrochemical Society on Duty-Free Importations

The November *Bulletin* of the American Electrochemical Society contained an item urging friends of educational institutions to protest against the passage of the so-called Bacharach bill repealing the privilege heretofore given colleges and universities of importing scientific apparatus duty free. Official announcement has since been made by W. S. Landis, president of the American Electrochemical Society, to the effect that the item in the *Bulletin* did not represent official society opinion. He states that this matter has not received attention from either the board of directors or the membership.

Helium Discussed at the 113th Meeting of the Rochester Section, A.C.S.

At East High School on the evening of Nov. 23 Dr. Richard B. Moore lectured at the 113th meeting of the Rochester Section of the American Chemical Society, and its guests, the Science Section of the New York State Teachers' Association, on "Helium, Its Preparation and Uses."

After giving a brief history of its discovery, Dr. Moore said that helium, like the other rare gases, was found to be inert. It had no particular use and so was of no importance, except to the scientist. But in 1915 Sir William Ramsey, then with the British War Department, wrote to Dr. Moore, saying he thought there was a great possibility of helium being used in observation balloons in place of hydrogen, providing a cheap source of it could be found.

After this country entered the war, acting upon Sir William Ramsey's suggestion, the Bureau of Mines, of which Dr. Moore is chief chemist, began to study the possibilities of helium for balloons. The natural gases in Texas, Oklahoma, Washington, Kentucky and other parts of this country contain from two-tenths to five-tenths per cent of helium and the Bureau of Mines established plants in Texas, the one at Fort Worth costing about \$2,000,000. The first shipment of helium was on its way to France when the armistice was signed. The plants in Texas are still in operation, for the army and navy recognize the great importance of this element. In the helium dirigible the engine can be put under or even inside, thereby getting a more direct drive and greater efficiency. When one considers that a large dirigible balloon costs about \$3,000,000, the discovery of a lifting gas that will not burn is of great importance. Dr. Moore illustrated his lecture with slides of the Texas plants. He also filled a small balloon with some helium, then held a match under it, showing the helium would not burn, as hydrogen does.

Short Course in Boxing and Crating of Materials to Be Given at Forest Products Laboratory

The Forest Products Laboratory at Madison, Wis., will give three courses in boxing and crating for representatives of manufacturing concerns beginning the first of the year. The object of these courses is to demonstrate to the manufacturers and packers the principles that underlie proper box and crate construction and develop economical containers that will deliver the contents to destination in a satisfactory condition and at minimum cost. The work will include drop tests to demonstrate characteristic failures of different kinds of boxes, drum tests to demonstrate the necessity of adequate nailing, relative holding power of different kinds of nails, methods of application and efficiency of steel strapping and the use of solid and corrugated fiber board and wire-bound boxes and crates. The dates for the next three courses are Jan. 10 to Jan. 15, March 7 to March 12, and May 2 to May 7. A co-operative fee of \$100 payable to the Forest Products Laboratory is charged to partly cover the cost of conducting the work. This fee does not include traveling and living expenses.

Needs a Ceramic Engineer

The Bureau of Mines is looking for a ceramic engineer to add to its staff at its ceramic experiment station at Columbus, Ohio.

General Fries Submits Annual Report

In concluding his annual report to Congress, General Amos A. Fries, head of the Chemical Warfare Service, made the following observations:

Just as every great earthquake is followed by a large number of lesser disturbances just so the World War has been followed by a host of minor upheavals, some of considerable importance and others just reflecting the general unrest caused by the overthrow of so many governments and other establishments of law and order. These disturbances during the past year have helped crystallize sentiment and force the sober-thinking man to conclude that wars are not yet past, much as he may long to see the arrival of that day in the world's progress.

The World War demonstrated that an enemy bent on aggression cannot be trusted to live up to any set rules of war. Methods of warfare develop just as all peaceful pursuits develop and they will continue to do so until such time as the nature of mankind as a whole has so changed that wars can be relegated to the past.

The United States has wisely decided to continue the Chemical Warfare Service with sufficient powers and with sufficient funds to develop its possibilities, not for aggression in any way whatsoever, but to insure that if American boys must ever again shoulder arms in defense of the liberties of their country they will do so on an equal footing with any other nation so far as chemical warfare is concerned.

The American is truly a sportsman and in war, as in sport, he is perfectly willing to stand any punishment providing he has an opportunity to give as well as take. The really serious objections to chemical warfare in the World War arose from the fact that the Central Empires, as well as most other countries, except the United States, had agreed not to use it. Under such circumstances a real sportsman who lives up to his agreement suffers a terrific handicap. No such handicap can occur in the future with the Chemical Warfare Service thoroughly alert to the possibilities of that arm and given power to prosecute its researches, its development and its training to the point where it knows that it is impossible for any other nation to have gone further. The knowledge among other countries that the United States is doing this will go a long way toward deterring them from forcing hostilities, knowing that the United States with its incomparable natural resources and highly developed manufacturing possibilities will be able to manufacture and to deliver on the field of battle a greater quantity of chemicals than any other single nation can manufacture and deliver, or indeed any other group of nations.

Louisiana Section, American Chemical Society

The regular monthly meeting of the Louisiana Section, American Chemical Society, was held at the Louisiana Museum, New Orleans, Tuesday evening, Nov. 16. The principal address was delivered by Dr. W. A. Noyes, who spoke on scientific research and the true nature of university work. He emphasized the value of research work in the higher institutions of learning in its application to the problems of the chemical industry as a whole for the benefit of all concerned, in contrast to the research work carried on in the individual industry for its own selfish ends.

The October meeting, the first of the season, was addressed by Dr. L. Lavedan, chief chemist, Hiller Vinegar Co., who spoke on "The Manufacture of Vinegar."

He pointed out the necessity of close chemical control to obtain efficiency in the production of vinegar. The percentage efficiency of acetic fermentation varies widely from plant to plant and operator to operator. The Southern climate is almost ideal for the work of acetic ferment. This ferment, or germ, must be nursed with great care if good service is expected. It must have regular meals of good quality. Sudden temperature changes are most harmful to production.

Conference on Colorado Clay

The Denver Civic and Commercial Association is convinced that full advantage is not being taken of the clay resources of Colorado. At the request of that organization, Dr. R. B. Moore, chief chemist of the Bureau of Mines, has arranged for a discussion of the situation in Washington. The meeting will be attended by Homer Vanderblue, the research director of the Denver organization; Dr. Moore; L. I. Shaw, assistant chief chemist; and R. T. Stull, superintendent of the bureau's ceramic station at Columbus, Ohio.

French Hydro-Electric Plant Completed

A large hydro-electric plant of 20,000 hp. has recently been completed by the Société Hydro-Electric of Lyon, a branch of the Compagnie du Gaz, Lyon, and the Compagnie Continentale Edison of Paris. The plant is located at Seyssel, Haute-Savoie, France. Importance is attached to the completion of this project because of the present scarcity and high price of coal, and likewise because of the effect it may have toward encouraging similar undertakings in France.

The plant is equipped with four turbines, each capable of developing a force of 5,500 hp. It is proposed to install another turbine at an early date, and thus increase the production to 27,000 hp., an amount that equals almost one-third of all the energy consumed under different forms by the city of Lyon.

Proposed Bill for an Association of Nitrate Producers of Chile

A cablegram from Ambassador Shea, Santiago, Chile, states that a bill has been presented to Congress by the Nitrate Commission of the Chilean Congress, to be discussed soon, for the creation of an association of nitrate producers of Chile. The bill provides for the control of freights and the purchase of ships, the purchase of materials for producers, and sales through direct agents. In addition it fixes prices and production, provides for technical work, direction of labor conditions, with a board of directors composed of eighteen men, six of whom will be appointed by the President. The government and members will contribute 10c. per 100 lb. produced until a capital of £5,000,000 is formed; the members must own an actively producing plant, and not be purchasers from other producers. An export duty of 6.76 pesos gold (1 peso = 36½c. United States currency) is fixed for every 100 kilos of nitrate exported; this is to be reduced one-half for members of the association.

Industrial Situation in Holyoke

In common with other parts of the country, the industries in Holyoke, Mass., have been affected by the recent business slump. The textile mills in the city have been forced to shut down part of the time and are now running only three or four days a week.

The paper industry has also been hard hit, particularly the fine-paper mills. Many of the mills have departments down for part of each week, while others have not been operating for some time. The coarse-paper market has not yet been influenced perceptibly by the present business conditions, but there are indications that it will soon feel the effects of these conditions, as the unfilled orders of some of the mills have decreased during the past month. The dull time of the

year, which includes the holiday season and inventory time, is close at hand, and the manufacturers do not see any prospect of betterment before the new year.

Many consumers of paper are not buying now, hoping that prices will go down. They have not large stocks ahead, and are buying only to such an amount as they find absolutely necessary. No great changes in prices need be expected at present in the high-grade writing papers, as raw materials and wages are still high. New rags, which are used in the highest grade writings, will probably remain at their present prices or may go higher, due to the fact that few of the textile mills in New England are producing any cuttings.

Although manufacturing conditions are unsatisfactory, there is as yet little unemployment. The manufacturers are trying to keep their organizations intact by having their mills running part time. There will probably be enough work to prevent any hardships to the employees this winter. There has been no talk of a reduction in wages, and there is no likelihood of any for some time.

Water, fuel and transportation conditions are satisfactory. The mills have enough coal for the coming winter, and unless unforeseen circumstances arise will get through fairly well.

Sherwin-Williams Co. Optimistic About Paint Industry

The sales of Sherwin-Williams Co. for the fiscal year ended Aug. 31 show a total of \$75,952,000, which is a gain of \$22,000,000 over the banner year of 1919. Comparison of the sales of \$51,817,000 for the American companies alone with the \$36,992,000 of the previous year shows a gain of 40 per cent.

According to the balance sheet the company has current assets of \$27,679,859 compared with current liabilities of \$6,636,738. It has \$992,855 in the cash account, and inventory of \$15,814,260. During the year a stock dividend of 50 per cent was declared so that the surplus account shows \$4,481,667 this year compared with \$7,175,311 a year ago.

Commenting upon business conditions, Walter H. Cottingham, president of the company, says:

We see no reason why there should be any immediate let-down in the sale of paints and varnishes where the unsatisfied demand is still great. There is an immense amount of left-over repainting to be done, and with the big building boom which is bound to come, we are looking forward to continued sales gains. In fact the figures since the start of the new year, Sept. 1, show constant increases over the figures of last year.

We know of no better barometer for business conditions than to study the operations of our own ten districts, twenty-seven divisions and seventy-five warehouses and distributing points, practically all of which report continued sales increases.

Merchants, it is true, have a tendency to order smaller stocks, but the wise merchants are not allowing their business to run down at the heels for lack of stock. They are not letting possible declines, which might amount to a few hundred dollars in their purchases, stand in their way of making several thousand dollars profit by having good stocks on hand to keep up a permanent business and give service to their customers.

In our own retail stores for the year just closed we showed a gain of 65 per cent, and since the new year started Sept. 1 there is an increase of 20 per cent over the record figures for the same period last year. This indicates an active consumer demand.

A group of our managers who recently toured the country report that in all sections they visited, with a few exceptions, they heard and saw only evidences of basic soundness and prosperity. This goes back to agricultural conditions in the last analysis.

Personal

Lieutenant Colonel WALTER C. BAKER has been transferred from the Coast Artillery to the Chemical Warfare Service and has been placed in charge of the supply division in the office of the Chief of the Chemical Warfare Service.

Lieutenant Colonel CLAUDE E. BRIGHAM has been transferred from the Coast Artillery to the Chemical Warfare Service and has been placed in charge of the administrative and personnel divisions of the Service.

WILLIAM W. COBLENZ, physicist of the Bureau of Standards, Washington, D. C., has been awarded the Janssen Medal by the French Academy of Sciences.

FRITZ J. FRANK, vice-president of the Iron Age Publishing Co., has been elected president of that company, following the resignation of William H. Taylor, who had been president and general manager for more than ten years. Mr. Taylor has resigned because of ill health, and has retired from active connection with the Iron Age Publishing Co. He went to *Iron Age* as general manager, after a group of publishers had acquired the ownership from David Williams. Previously, Mr. Taylor had been connected with various trade and engineering publications over a period of fifteen years, having for a time been vice-president of the McGraw Publishing Co. and later president of the Taylor Publishing Co. of Chicago, which consolidated *Engineer* and *Steam Engineering*. He and his associates on acquiring *Iron Age* separated what had long been a hardware department of that journal, and established it as *Hardware Age*. Mr. Frank has been with the Iron Age Publishing Co. since 1910, after an active association with other trade publications, among them *Colliery Engineer* and *Mining and Scientific Press*. He has a wide acquaintance in the iron and steel and machinery trades, is experienced in business journalism, and is thoroughly committed to the traditions and standards of *Iron Age*, which belongs in that progressive group of business publications which put editorial service to the reader as the basis for substantial and sound publishing development.

G. K. HERZOG has recently been transferred from the research department of the Electro Metallurgical Co., Niagara Falls, N. Y., to the Itaynes Stellite Co., Kokomo, Ind., in charge of the research and development department.

A. STUART KELSEY is now assistant research chemist with the Standard Textile Products Co. The present investigation is at the Buchanan, N. Y., factory.

DEXTER S. KIMBALI, professor of industrial engineering at Cornell University, Ithaca, N. Y., spoke before the Detroit Engineering Society on Dec. 3 on "A Broader Field for the Engineer."

Dr. SAMUEL A. MAHOOD, formerly senior research chemist of the Forest Products Laboratory, Madison, Wis., is now associate professor of organic chemistry, Tulane University, New Orleans, La.

CHARLES A. MUNROE, vice-president of the People's Gas Light & Coke Co. of Chicago, has been elected president of the American Gas Association.

C. G. SELDEN and C. E. ANDREWS of the Walker Chemical Co., Pittsburgh, Pa., have recently sailed for England and the Continent on business for the company.

Dr. GERALD L. WENDT, of Chicago University, has just returned from a Western trip. He spoke before the Tri-City Chemists' Club at Davenport, Iowa; the Kansas City, Neb., Omaha and Ames Sections of the American Chemical Society on "Electrometric Titration." At the University of Nebraska and Grinnell College, he delivered lectures on "Activation and Elementary Gases" and the "Nature of the Atom."

Book Reviews

WHAT'S ON THE WORKER'S MIND. By Whiting Williams, personnel director Hydraulic Pressed Steel Co. 329 pp., illustrated. New York: Charles Scribner's Sons. Price \$2.50.

Whiting Williams was not the ordinary kind of personnel director. He wished to get a first-hand impression of the man in overalls for the general good in solving the problems of capital and labor. Having arranged for his salary as personnel director to go to his family, he went forth with \$25 to earn his living as a common laborer for seven months. The observations from his experiences have been set down in this interesting book. Mr. Williams' previous experience of life had been as assistant to the president of Oberlin College and as executive secretary for the Cleveland Welfare Federation.

This alert looking young American got into a sheepskin overcoat and let his face go unshaved until he looked the part. During seven months in 1919 he worked in steel mills, coal mines, railroad yards, iron mines and shipyards. As soon as he had walked the plank of "the good ship 'White Collar,'" he found himself in a different world. He learned the feelings of men herded outside the hiring gates at the mercy of bullying guards, and of the irritating inadequacy with which many firms deal with their employees. At one large steel plant where 10,000 men are employed, "the young clerks supposed to do the hiring gave most of their time to tickling the backs of the necks or the much-exposed chests of the young stenographers," while the applicants, to whom jobs and proper consideration meant a great deal, could talk to the clerks only through two misplaced holes in plate-glass.

In all the jobs where he worked the author found much waste and inefficiency resulting from the bad influence of the wrong kind of bosses. So many corporations have elevated the wrong type of individual over his fellows that bitterness and enmity have driven out co-operation. Leaders instead of drivers are needed for foremen, the author makes plain, and chronic fatigue does not pay, as efficiency engineers have agreed since Taylor conducted his famous experiments in loading pig iron. The average unskilled worker is lacking in enthusiasm for his work, because he does not understand what it all means, and generally no inspiration is to be obtained from the foreman.

Strange to say, higher wages are not the solution of labor unrest, declares Mr. Williams. "What makes the wheels of all of us go 'round is the desire for a satisfying sense of our own individual worth-while-ness, and the cause of practically all the friction between people, and especially between people of different groups and statuses, is to be found in offended or obstructed self-respect, injured pride and hurt feelings." This is a lesson that employers are extremely slow at learning; the truth has been pointed out again and again, yet even so well stated an argument as Mr. Williams' will probably be heeded by only a few. He continues, "We give to the dollar altogether too great an importance when we consider it the cause either of men's industry or their intrigue, their virtues or their vices. The dollar is merely an especially convenient and simple means for facilitating the measurement of a man's distance from the cipher and insignificance among his fellows. If it does not serve that end it is not sought beyond the narrow limits required for the daily bread—as where conspicuous leisure proves more valuable to this end and so causes loafing in exactly the same way that the standing which the dollar can buy for the employer brings him down diligently on time every day to his desk. Beyond a certain point, dependent upon the standing and status which the dollar can buy in the community, the increase of wages is thus quite as likely to lessen as to increase effort." Incidentally, much the same kind of argument has been advanced by the present reviewer during the past several years in articles

in *Engineering News-Record, Mining and Scientific Press, and Engineering and Contracting*.

Mr. Williams emphasizes the great good to the community accruing from the worker's self-respect, the self-respect that keeps "the millwright at his bench every working day, an upright, forward-looking and sincere worker and citizen." When workers lose their self-respect, says the author, from mistreatment under grouchy foremen, or from having to stand at hiring gates, or from being herded out of their rights by pompous officials, there is a certain paralyzing effect which destroys the morale of a significant part of the industrial community.

In the last several chapters of the book Mr. Williams makes some definite suggestions for bettering conditions in industry. He is opposed to the twelve-hour day and seven-day week which prevail in much of the iron and steel industry, because chronic tiredness and temper do not pay. The worker should have more security of steady work, and should not be hired and fired as a commodity to which nothing else is due—a point which Samuel Gompers has long emphasized. The so-called "Americanization," which is so glibly prated about, should be taught not only by English classes and welfare officials, but by actual demonstration of what Americanization means, as when a foreman commands, a judge instructs, a newspaper reports and a salesman sells. In other words, the officials elevated to positions of importance in our communities should be picked more carefully for their influence in illustrating the best ideals of America.

The final picture of the worker that Mr. Williams gives is that of a human being neither lazy nor avaricious, but willing to co-operate if he can understand the work and will be rewarded fairly for giving the best that he has in him. The worker is much like the rest of us, in fact, though with much less chance to learn what he wants to know about things. On the other hand he "can see fine points in a dull and monotonous job with an eye that should shame us," and he has a naïve wish to be useful and to be recognized as useful. Such considerations as these should be given sincere thought by employers. The problem of capital and labor is assuming menacing proportions. If arguments such as Mr. Williams' are not heeded, dire disaster may come to American industry. Employers should use more imagination and prescience than has been the custom among their kind. More men like Whiting Williams should be promoted to the critical positions in industry.

P. B. McDONALD.

GAS AND FUEL ANALYSIS. By *Alfred H. White*, professor of chemical engineering, University of Michigan, Ann Arbor. International Chemical Series; second edition, revised and enlarged. Pp. xiii + 304; 54 figures. New York and London: McGraw-Hill Book Co., Inc., 1920. Price, \$3.

The author of this book undertook an exceedingly difficult task when attempting to combine the functions of a text book with those of a reference volume. His purpose to this end is stated in the preface of this second edition as follows: "The needs of students have been kept in mind, but the intention has also been to make the book one which would supply the practicing engineer and chemist with the most necessary information." Despite the difficulty involved, the work succeeds admirably in presenting for student use as well as for experienced workers the important types of gas- and fuel-testing equipment and the methods for their successful use.

The second edition profits greatly by the extended additions which have been made from recent work by the Bureau of Mines, Bureau of Standards and several technical societies, notably the American Chemical Society and the American Society for Testing Materials. In most instances the methods described are the latest and best which have found general practical acceptance. In only a few cases have novel methods not yet generally used been permitted to displace or overshadow the better recognized procedures. It is evident that the author has carefully kept in mind the fact that one who will use the book will want a description of

methods and equipment generally available and acceptable, rather than more novel procedures not yet accepted or for which apparatus is not usually available.

If a more frequent and elaborate attention to interpretation of analyses had been possible, this would add materially to the value of the text, both for the student and the practical worker. Because of the very general application of the work, however, such discussion of interpretation of results would have been difficult and possibly at times misleading. The author may, therefore, be excused for this omission.

It is a little unfortunate that the treatment of absorption methods for gas analysis is so limited. In this particular chapter many of the most valuable chemical procedures are mentioned, but there is no presentation of the more valuable recent types of apparatus for use in this field. The single illustration of this chapter presents an old-style Hempel outfit of a type showing evidence of such assembly as might be expected from the undergraduate student in college. The idea all too generally held that the Hempel apparatus is superior in accuracy to equipment of the Orsat type, using numerous modern styles of pipette, should not receive this encouragement. This fallacy is still further encouraged by the presentation of the Orsat apparatus in two modifications, both old and out of date, in the chapter on technical gas analysis, whereas in the chapter on exact gas analysis there is no hint by illustration as to the form of pipette which is recommended. This lack will perhaps be offset in any course of instruction by proper aid from the lectures and laboratory advisers; but for use of the practical man outside the college there is nothing to suggest that exact gas analysis is made as much more difficult by improper selection of pipette as by inferior burette or improper technique.

Successful gas and fuel analysis is chemically and physically of extreme theoretical simplicity. Success demands care and skill rather than much knowledge. The apparatus and its manipulation demand more finished technique on the part of the operator than almost any other type of chemical analysis commonly used. The opportunity for error on chemical grounds is almost *nil* by comparison. If one recognizes these points as a result either of experience or careful instruction, he can well take this text as a most valuable guide for his work. If he does not take it, it would be difficult to say what else could be recommended as a substitute in American literature.

R. S. MCBRIDE.

KAOLIN OF INDIANA. By *W. N. Logan*, State Geologist of Indiana. 132 pp., cloth; 43 illustrations and colored plates. Indianapolis: The Department of Conservation, State of Indiana, Division of Geology.

This report is devoted to the geological conditions of the occurrence, the origin, geographical distribution, the physical and chemical properties and the uses of kaolin in the state of Indiana. The occurrence of large beds of kaolin in southern Indiana has long been known. Its extremely pure and crystalline appearance, together with its interstratification with sedimentary rocks, has been the cause of a great deal of speculation concerning its origin and geological occurrence. Some have suggested that a coal bed at one time occupied this horizon and was burned out, while others see in this unusual deposit the residue of a decomposed limestone. A new theory of origin is proposed in the report.

Although this clay has been used intermittently for several years, it was left for the author to make a detailed survey of the deposits and work out its origin. Extensive laboratory tests have been made of the chemical and physical properties of the clay. Samples have been tested in a large number of laboratories connected with industrial plants and Government bureaus. Topographical and geological maps of the areas in which the kaolin is found are embodied in the book.

The matter is well presented and holds much of interest to ceramists and clayworkers.

CHESTER H. JONES.

NEW INDUSTRIAL UNREST. By *Ray Stannard Baker*. 232 pp. New York: Doubleday, Page & Co.; 1920. Price, \$2.

So much of the literature on industrial unrest has been written by interested parties that a discussion by a trained writer cannot fail to have an interest and a value of its own. It is difficult, however, for anyone to write on such a subject without being guided, to some extent at least, by personal opinions, and to many it will appear that Mr. Baker writes from the viewpoint of a sympathizer with organized labor rather than an impartial observer. The first twelve chapters of the book are more in the nature of a description and an interpretation of recent events in the industrial world of America. The six concluding chapters are largely devoted to a discussion of the shop-council system and its application both in Europe and in America. In this the author is developing a line of thought that is not particularly popular in our industrial world today, since, except in certain specific industries, shop councils are not in favor in America with employers or, more especially, with employees. The author recognizes the difficulty of indicating any simple solution of a problem of such complexity and appears at his best in his concluding paragraph, in which he says:

"In another sense, there is a solution. It consists in the attitude, the spirit, which one maintains toward the labor problem—an adventurous, inquiring, experimental attitude, ever hospitable toward new facts; and a generous and democratic spirit. I wonder if men can find this solution in its completeness without some high faith in God, and some vital interest in their fellow men." T. T. READ.

THE MANUFACTURE OF SULPHURIC ACID IN THE UNITED STATES. By *A. E. Wells and D. E. Fogg*. 216 pp., 36 figures and 15 plates. Washington: Superintendent of Documents.

This bulletin, No. 184, is a fine report on the investigation of the sulphuric acid industry by the Bureau of Mines. It will be gladly received by the men in the industry, especially by those who have not had the opportunity of making many observations due to limitations in their outside connections. Sulphur, pyrite and pyrrhotite and byproduct sources of SO₃ are treated in an adequate manner. Production methods and equipment for the chamber and contact processes are described in fifty pages each. A remittance of 40c. is asked to help defray the costs of the distributing office.

WALLACE SAVAGE.

Current Market Reports

The Chemical and Allied Industrial Markets

New York, Dec. 6, 1920.

It could hardly be said that the general trend of affairs changed materially in the chemical market during the past week. As a whole trading was along quiet lines with the tone fairly steady. Continued absence of forced selling, however, is establishing a better feeling, while stronger confidence is gaining in business prospects for 1921. Miscellaneous buying inquiries for domestic and export needs were reported for *bichromate of soda* and these have strengthened the spot market and nearby positions to a perceptible degree. Sales for material ex store reached 9½c. per lb., while January shipments were quoted firm by dealers at 10½c. per lb. Leading producers named 15c. per lb. for contracts over 1921, and this price also held good for export. Resale lots for *aluminum sulphate* were offered at 3½c. per lb. for the iron-free grade, while rumors were current that a price of 3½c. per lb. could be had on firm business. Moderate quantities of the commercial type were quoted at 2½c. per lb. Small lot trading of *oxalic acid* was reported at 18c. per lb., with sellers asking up to 19c. per lb. The demand is very slow and buyers show little interest

in quantities exceeding actual wants. *Formaldehyde* inquiries for domestic and export requirements reached the market in more volume than any chemical on the list. Odd lots were reported to have sold at 18½c. per lb. early in the week, with a pronounced strengthening during the latter half. At the close the market appeared quite steady at 19c. per lb. Jobbers are holding standard brands of solid *caustic soda* at \$3.75@4 per 100 lb., and reported scattered transactions at these figures. The movement in this chemical has been along quiet lines of late and the tendency to bring buyers into the market was noticed when dealers quoted figures as low as \$3.65 per 100 lb. Manufacturers' views on contracts remain unchanged at 3½c. per lb. basis 60 per cent f.o.b. works for 1921 shipment. Producers continue to name 18c. per lb. works for prime American *chlorate of potash*, while large resale lots of imported and domestic material are being offered freely at various prices down to 13c. per lb. with no actual trading noted.

COAL-TAR PRODUCTS

Prominent factors in the crude and intermediate markets are viewing conditions with more optimism. The volume of cheap resale material seemed to be diminishing in one quarter and another and some producers are expecting to name contract prices over next year in a very short time. The general feeling seems to be that considering the cost of production, the nearness of present prices to those of the pre-war period and the heavy demand that will be noted when normal conditions appear will automatically prevent any lower range, but will show good prospects of advances in a majority of commodities. Trading during the past week was of the quiet routine nature that has followed along the same lines for the past month, with buyers exhibiting timidity in most directions. The crude market is uncertain. Some items are holding steady, while others are in little demand and reflecting an easy tendency as to price. *Benzene*, c.p., is moving in fair volume with drums held at 35c. per gal. The 90 per cent is offered at 32@33c. per gal. *Naphthalene* producers have named 9@10c. per lb. for contracts over 1921. Consumers did not come into the market with this announcement, although a more stable condition is looked for in the near future. Inquiries for *alpha naphthol* are attracting attention lately and the few factors making it report the supply very limited, with the crude grade held at \$1.10 per lb. and the refined at \$1.45 per lb. On account of the general quiet conditions throughout all the markets and the extra receipts of *anthracene* from abroad, the supply of this product has been much easier of late and buyers have been able to force holders to make considerable concessions in some quarters. The 80 per cent grade ranged from 85c. to \$1 per lb. Domestic demand for *alpha naphthylamine* remained quiet, while resale lots were not being offered as freely and producers continued to quote 47@50c. per lb. A quiet routine business is being noted in *Dimethyltoluene* in smaller lots and prices held steady at 27@30c. per lb. in the absence of any low-priced resale stocks. There is a very quiet market reported in *orthotoluidine*, with consumers taking only limited quantities to cover present needs. Prices are quoted unchanged at 30@32c. per lb.

Chemical Outlook for 1921

The chemical and allied markets have reflected flashes of activity lately, and those eager to take an optimistic view of these demonstrations believe that the long period of liquidation with all its depressing influences is nearing its end. Producers do not expect any active resumption of business similar to that of the early months of 1920, but feel confident that the new year will bring with it a vast improvement in the industrial conditions of the country. The first quarter of 1921 is looked forward to furnish the change, but a conservative, steady expansion in general business circles is expected prior to that time. The probability of easier money rates and loans from leading financial institutions is a probable factor in the business situation. Captains of finance have expressed their intentions of relieving any intense situation that may arise, and are ready with plenty of available funds. This will undoubtedly allow the launching of new enterprises and the elaboration of plans

which were formulated some time ago by leading chemical manufacturers. It stands to reason that heavy liquidation in securities and in practically every important commodity in the country has released a large supply of funds which bankers will be eager to place as soon as yearly dividends and settlements are completed.

CREDITS TO FOREIGN BUYERS

America is also confident that ways and means will shortly be established for the granting of extended credits to foreign buyers. This would relieve the tight situation confronting our present export trade and foster new foreign buying. While this might temporarily work against exchange rates, it is absolutely essential that European countries be allowed to purchase raw products here, as their supply is so small that it is retarding greatly their progress in a return to normal trade. Prominent chemical producers have frequently expressed their belief that Europe is sorely in need of raw materials of all kinds.

LABOR CONDITIONS

Labor conditions are still abnormal. Organized labor has undermined unionism by its drastic demands for continuous increases. Tanneries, soap factories, textile mills and dye plants have been compelled to close their doors at various times because the decline in price of finished products was not reciprocated by labor. The result is that labor will be enrolled at a price more commensurate with the cost of finished commodities when these plants resume operation. It is already significant that labor is entertaining a more conciliatory view, and as the cost of living comes down a more equitable understanding will prevail.

NO REASON FOR PESSIMISM

Americans are not inclined to pessimism. A country with over 100,000,000 persons to be clothed, fed and housed will not find conditions stagnant for an indefinite period. Depression has featured the chemical industry since last May. Although large losses have been taken, there are still a few more to be assumed. The sooner this is realized the better; but the dark streaks are gradually dwindling away and American industry is coming into its own before long primed for its battle of world-wide trade supremacy.

The Baltimore Market

Baltimore, Dec. 4, 1920.

Little change can be reported in the local market on fertilizer raw materials. Baltimore fertilizer manufacturers depend largely on the Southern territory as an outlet for their goods. Because of the sudden break in the price of cotton, Southern planters are generally in a bad financial condition, and as a consequence the manufacturers are having little success in collecting for goods shipped during the past season. As a direct result of this tight money situation in the fertilizer industry, comparatively small tonnages of raw materials are being purchased and the purchases that are being made are strictly on a hand-to-mouth basis. At this time it would appear that the tonnage of fertilizer used in the South will be greatly curtailed.

We may sum up the situation by saying we have a waiting market with good stocks of material in evidence and no particular interest being shown in them.

Acid Phosphate. The market may be quoted nominal at \$16.50 per ton, basis 16 per cent bulk, run-of-pile. Round tonnages to fertilizer dry mixers could be closed as low as \$16 on this basis.

Nitrate of Soda. Importers are quoting the market nominal at \$2.90 per 100 lb. ex vessel Atlantic ports. Resale lots of round tonnages, however, have been recorded as low as \$2.75. The market on nitrate at this time is quite uncertain and the trend seems to be downward.

Sulphate of Ammonia. Resale lots have been offered this week as low as \$4 per 100 lb., basis 25 per cent, in single or double bags f.o.b. shipping point. Large stocks are not in evidence at this time.

Potash.—A number of resale parcels of German and Alsation salts have been placed before our trade. We quote the market nominal, muriate \$1.80 per unit, kainit and manure

salts \$1.75 per unit, all ex vessel North Atlantic ports. Nebraska potash is being quoted nominal at \$2 per unit f.o.b. mines, in single bags.

Fish Scrap.—There has been no further change in the market on machine-dried unground menhaden fish scrap. This commodity is still being quoted and occasional sales are effected at \$4 per unit of ammonia and 10c. per unit B. P. L. ex schooner, Baltimore, in buyers' bags. A good stock of unground scrap is still being held by the fish factories. This is a very unusual situation, as the scrap production is usually entirely absorbed by the end of the fishing season. We have previously reported that all the factories on the Chesapeake Bay have "cut out" for the year.

The Iron and Steel Market

Pittsburgh, Dec. 3, 1920.

The reductions in bars, shapes and plates to the Steel Corporation level made a week ago today, as noted in last report, have not induced the placing of an appreciable amount of business, nor indeed was it expected that any great amount of business would result at once. It was simply a case of the independents being clearly in an untenable position as to prices, with the incentive for maintaining prices removed, the incentive previously having been that of being able to make contract deliveries. Contracts had run out or customers were refraining from furnishing any further specifications. At this writing two or three of the Eastern independents have not yet reduced their quotations, and this may indicate that they still have some contract tonnage. As to the market, there is no range of prices, since any one of the sellers at the Steel Corporation prices could take care of the entire demand now found in the market.

Monday of this week a large independent producer of wire in the Pittsburgh district came down to the Steel Corporation prices, 3.25c. for plain wire and \$3.25 for nails. Other independents have shown no haste to make formal reductions, their position being that they still have some contract business on books, while there is no important business in the market to be lost by not meeting the situation. The entire market for wire products is now quotable as follows: Wire nails, \$3.25; plain wire, 3.25c.; galvanized wire, 3.95c.; painted barb wire, 3.65c.; galvanized barb wire, 4.35c. The nail price is that of the Industrial Board schedule, but the price on wire is \$5 per ton above the Industrial Board figure, the American Steel & Wire Co. having made an advance of that amount last August.

MANUFACTURED STEEL PRODUCTS

Adjustments are naturally to be expected in manufactured steel products, in harmony with the declines in the hot rolled material. Last Monday two producers of cold-finished steel bars formally reduced their quotations by \$8 a ton, from 4c. to 3.60c., and others intimated that they would reduce their quotations whenever attractive business should be offered. On Wednesday a leading producer of bolts and nuts announced new discounts, representing reductions from prices previously prevailing of approximately 20 per cent. Rivets, spikes, chain, etc., are awaiting readjustment.

CONTRACT ADJUSTMENTS

In most cases when producers have made reductions it is either formally stated or is inferred that any unfilled business remaining on books will be adjusted to the reduced prices. This is the common practice in finished steel products. While contracts are made, the contract is largely in the nature of an option given the buyer, who by refraining from specifying can nullify the contract. Long ago a contract for three months, six months or a year was regarded practically as involving simply a lump amount, but a few years ago the mills instituted a change, whereby the contract required specifications in equal monthly quantities, and any tonnage unspecified monthly would automatically be canceled. The option feature of the arrangement is usually extended so that a mill will accept cancellation when the actual specifications have been filed, provided manufacture has not been commenced. In semi-finished steel and pig iron the sales practice is different, contracts being regarded as

absolutely binding, though as a matter of accommodation postponement of delivery is frequently permitted. Several years ago the sheet mills instituted what they denominated a great reform, a binding contract being adopted, providing for reciprocal damages, against the mill if delivery was not made and against the buyer if specifications were not furnished and the material accepted. It is doubtful, however, whether the sheet mills will seriously attempt to enforce contracts at this time.

PIPE AND SHEETS

In tin plate, bars, shapes, plates and wire products the independent market is now down to the Steel Corporation market, the change having occurred quickly and proving much less spectacular than might have been expected. Of the prominent rolled products rails, sheets and pipe still present two markets. In rails the Steel Corporation has not formally announced its prices, but these will doubtless be 6.20c. for galvanized sheets, these prices being \$10 a ton with the Industrial Board schedule, and presumably the independents will make the same prices.

In sheets the market continues to decline rapidly, the decline in the past week being half a cent a pound or more. Several independents are now willing to take business at 4.05c. for blue annealed sheets, 4.85c. for black sheets and 6.20c. for galvanized sheets, these prices being \$10 a ton above the Steel Corporation or Industrial Board prices.

In pipe, which has been by far the strongest of the finished products, the Steel Corporation and independents have been only \$7 a ton apart, the Steel Corporation's prices representing a basing discount of 57½ per cent, while the list issued by the independents early in the year is on a 54 per cent basis. Independents have at times secured large delivery premiums above their regular list. The market is in such condition that the independents may not have occasion to reduce for many weeks.

Yesterday the American Sheet & Tin Plate Co. had its semi-annual opening of order books, whereby contracts will be made with manufacturing consumers for the first half of 1921, prices being the Industrial Board prices continuously maintained by the Steel Corporation: Tin plate, \$7 per base box, 100 lb.; blue annealed sheets, 10 gage, 3.55c.; black sheets, 28 gage, 4.35c.; galvanized sheets, 28 gage, 5.70c. As the company will carry over about three months of work, the deliveries to be arranged on new contracts will be practically for the second quarter.

PIG IRON

Declines in pig iron have continued. Although there has been scarcely any incentive by way of inquiry, furnace quotations are down in the week by \$2.50 on bessemer and \$2 on foundry and basic, to \$37 for foundry, \$35 for bessemer and \$33 for basic, f.o.b. valley furnaces, freight to Pittsburgh being \$1.96. Again it is suggested by furnace interests that the remainder of the pig iron decline will be relatively slow, and doubt is even expressed whether basic iron will be down to \$30 before April 1. As to the eventual bottom of the pig iron market, before an upturn occurs, practically all views lie within the limits of \$25 and \$30 for basic and foundry grades.

THE FUTURE

The iron and steel market generally is altogether too stagnant for the condition to last. After a period of activity the market can be entirely inactive for a time, but in a prolonged period of dullness there must be some buying from day to day. On this basis a moderate revival in demand is expected to occur immediately after Jan. 1, but no general buying movement, with any stiffening in prices, is to be expected before April at the earliest. While the decline in the independent market to the Steel Corporation level was universally expected, hardly anyone expects the independents to stop at that level, and it is probable that more or less shading will eventually develop, though perhaps not to an extent that would require the Steel Corporation to reduce its prices. Apart from the matter of prices, which is a detail the steel producers are bright enough and quick enough to take care of, no heavy demand for steel can be expected until the country has completed its readjustment and the cost of consuming steel has been reduced.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Continental Gin Co., 3330 10th Ave., has awarded the contract for the construction of a 1-story, 132x400 ft. foundry and a 1-story, 100x300 ft. machine shop, to the H. K. Ferguson Co., 6523 Euclid Ave., Cleveland, O. Estimated cost, \$500,000.

Connecticut

BRIDGEPORT—The city has awarded the contract for furnishing and installing machinery and equipment for the proposed sewage disposal plant on Harborview Ave., Black Rock Station, to the Sanitation Co., 50 Church St., New York City. Estimated cost, \$19,500.

HARTFORD—The Bd. of Water Comrs. will receive bids January 10 for furnishing 21,000 yd. of filter sand and about 12,000 yd. of filter sand for filter beds. C. M. Saville, engr.

WEST HAVEN—The Union School Dist., Orange, is having plans prepared for the construction of a 3-story high school. A chemical laboratory will be installed in same. Estimated cost, between \$350,000 and \$400,000. R. W. Foote, 185 Church St., New Haven, archt.

Indiana

INDIANAPOLIS—The Pioneer Brass Wks., 424 South Pennsylvania St., is having plans prepared for the construction of a 1-story machine shop. J. H. Brinkmeyer, pres. C. Grossman, engr.

MICHIGAN CITY—The Steel Fabricating Co., Harvey, Ill., is building a plant here.

Iowa

SHELBY—The Bd. Educ. has awarded the contract for the construction of a 2-story, 120x130-ft. high school, to J. F. Wakefield Co., 750 Brandeis Theatre Bldg., Omaha, Neb. A chemical laboratory will be installed in same. Estimated cost, \$119,900.

Maryland

AMCELLE (Baltimore, P. O.)—The Amer. Cellulose & Chemical Mfg. Co. Ltd., 681 5th Ave., New York City, has awarded the contract for the construction of a 1-story plant, to the G. A. Fuller Co., 175 5th Ave., New York City. Estimated cost, \$200,000.

BALTIMORE—The Metal Package Corp., Wolfe and Thames Sts., plans to construct a tinplate and lithographing plant.

Massachusetts

NATICK—The Griess Pfeiffer Tanning Co. of Massachusetts, P. O. Box 271, plans to build an addition to its leather manufacturing plant.

Michigan

DETROIT—The Anchor Bldg. Co., c/o F. J. Winter, archt., 2331 Dime Bank Bldg., is having plans prepared for the construction of a 2-story 50x100 ft. paint shop on West Grand Blvd. Estimated cost, \$50,000.

DETROIT—The Bd. Educ., 50 Bway, will receive bids until December 21 for the construction of a 5- and 7-story, 250x350 ft. technical high school on 2d Ave. and High St. A chemical laboratory will be installed in same. Estimated cost, \$2,500,000. Higginbotham, Malcolmson & Palmer, 405 Moffat Bldg., archts.

DETROIT—G. W. Graves, archt., 43 John R. St., will receive bids until Dec. 10 for the construction of a 1-story, 90x200-ft. foundry for the Zenith Fdry Co., Miller Ave. Foundry equipment will be installed in same.

Minnesota

MANKATO—The Immanuel Hospital Association plans to build a 2- or 3-story addition to hospital. A chemical and pathological laboratory and an X-ray department will be installed in same. Estimated cost, \$150,000.

ST. PAUL—The city has awarded the contract for 30,000 lb. of liquid chlorine for treating city water in 100-lb. cylinders, to Noyes Bros. & Cutler, 6th and Sibley Sts., at 9c. per lb. Noted Oct. 27.

New York

ITHACA—Cornell University plans to construct a 5-story, 190x268-ft. chemical building. Gibb & Waltz, Trust Co. Bldg., archts.

YONKERS—The Hudson & Rubber Corp., Proctor Bldg., has awarded the contract for the construction of a 3-story factory on Nepperhan Ave., to James Mitchell Inc., 76 Montgomery St., Jersey City, N. J. Estimated cost, \$300,000.

North Dakota

JAMESTOWN—The Bd. Educ. will receive bids Jan. 1 for the construction of a 3-story, 125x195 ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$175,000. Shannon, Boyd & Boyd, engr.

Ohio

CLEVELAND—The Atlas Fdry Co., 7275 Shaw Ave., has awarded the contract for the construction of a 1-story, 37x45-ft. addition to its foundry, to D. Gilchrist, Peoria. Estimated cost, \$25,000. Noted Oct. 27.

MT. VERNON—The C. & G. Cooper Co., 11 Bway, New York City, has awarded the contract for the construction of a 1- and 2-story foundry and machine shop, to D. P. Robinson & Co., Inc., 125 East 46th St., New York City. Estimated cost about \$400,000.

Oklahoma

BARTLESVILLE—The Bd. of Comrs. will soon receive bids for the construction of a sewage disposal plant, etc. Estimated cost, \$200,000. E. D. Kirkpatrick, engr.

SAPULPA—The city is having plans prepared for the construction of a dam, reservoir, filter basins, force main, distributing reservoirs, etc. The Halway Eng. Co., 230 Lynch Bldg., engr.

Pennsylvania

LEWISTOWN—The Pennsylvania Wire Glass Co., Pennsylvania Bldg., is having plans prepared for the construction of a 1-story, 175x600-ft. glass plant. Equipment will be installed in same. P. A. Hayes, Pennsylvania Bldg., archt.

Rhode Island

PAWTUCKET—The Perry Spring Mineral Water Co., 3 Charlton Ave., has awarded the contract for the construction of a 2-story, 10x40 ft. addition to its plant, to the C. I. Higney Constr. Co., 357 Westminster St., Providence. Estimated cost, \$15,000.

Texas

EASTLAND—The city will soon award the contract for the construction of a sewage disposal plant to include an Imhoff tank, sprinkling filter and sludge bed. J. A. Wright, city engr.

Virginia

QUANTICO—The Bureau of Yards & Docks, Navy Dept., Wash., D. C., received bids for the construction of an incinerator plant to include a septic tank, etc., at the Marine barracks, here, from the King Lumber Co., Charlottesville, \$41,800; Hyde & Baxter, 1311 G. St., N.W., Wash., D. C., \$46,000; Newport Constr. & Eng. Co., Newport News \$48,310. Noted Nov. 3.

West Virginia

WHEELING—The Wheeling Axle Co. has awarded the contract for the construc-

tion of a 2-story addition to its axle factory on 27th St., to J. E. Moss. Estimated cost, \$6,500.

Wisconsin

GRANVILLE—The T. J. Moss Tie Co., Security Bldg., St. Louis, Mo., has awarded the contract for the construction of a 1-story, 40x200-ft. creosoting plant, etc., to J. L. Stannage, 144 Oneida St., Milwaukee. Noted Nov. 24.

MILWAUKEE—The Milwaukee Children's Hospital, 219 10th St., is having preliminary plans prepared for the construction of a hospital building, etc., on Grand Ave. A chemical laboratory will be installed in same. Estimated cost, \$450,000. Scott & Mayer, Colby-Abbot Bldg., archts. and engr.

TWO RIVERS—The Bd. Educ. will soon award the contract for the construction of a 3-story, 80x155-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$400,000. J. D. Chubb, 109 North Dearborn St., Chicago, Ill., archt.

Ontario

BROCKVILLE—The Provincial Bd. of Health plans to construct a filtration plant. Estimated cost, \$50,000.

PEMBROKE—The McGuire, Patterson & Palmer, Ltd., 343 Dorchester St. W., Montreal, has awarded the contract for the construction of a match factory, to Fraser Hume & Co., Ltd., 83 Craig St. W., Montreal. Estimated cost, \$5,000,000.

PORT DALHOUSIE—The city has awarded the contract for the construction of a sewage disposal system, etc., to L. M. Smith, 58 Howard St., Toronto. Estimated cost, \$45,000.

ST. CATHERINES—The Kinkth Paper Co., Welland Canal, has awarded the contract for the construction of a 2-story addition to its paper factory, to the Tremble Co., Thorold St. Estimated cost, \$25,000.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29, 1921.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS is holding its winter meeting at New Orleans, Dec. 6 to 9. Headquarters are at the Hotel St. Charles.

AMERICAN PHYSICAL SOCIETY will hold its annual meeting, beginning Dec. 28, at Chicago, it being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS 1920 annual meeting will be held in the Engineering Societies Building from Dec. 7 to 10 inclusive.

COMMON BRICK MANUFACTURERS' ASSOCIATION OF AMERICA will hold its annual meeting at the Hotel Pennsylvania, New York City, Jan. 31 to Feb. 4.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at the Stadler Restaurant, Newark, N. J., the second Monday of every month.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Dec. 10, American Chemical Society, joint meeting with Society of Chemical Industry; American Electrochemical Society and Société de Chimie Industrielle; Jan. 7, American Chemical Society; Jan. 14, Society of Chemical Industry, Perkin Medal award; Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society, Nichols Medal award; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Supreme Court Declares Hydrogenation Patents Invalid

LAST week the United States Supreme Court handed down a decision of epoch-making importance to the chemical industry in the case of PROCTER & GAMBLE vs. the BERLIN MILLS Co. relating to the hydrogenation of cottonseed and similar oils. In a unanimous opinion in favor of the defendant the court declared invalid claims 1 and 2 of the Burchenal patent for the production of a homogeneous lard-like food product consisting of a partly hydrogenated vegetable oil such as from cottonseed. The case practically turned on the interpretation of the words "homogeneous" and "lard-like."

PROCTER & GAMBLE'S suit against the BERLIN MILLS Co. for alleged infringement of a product made under the Burchenal patent was instituted in 1915 and has attracted widespread attention on account of the prominence of the litigants and the far-reaching importance of the decision when it should be rendered. The plaintiff obtained a favorable decision in the Circuit Court of Appeals, but the defendant succeeded in appealing to the Supreme Court on questions of law. We believe this is one of only seven cases in which the Supreme Court has reviewed an opinion of the Circuit Court unless conflicting opinions had then been rendered.

We hope later to present a more extended review of this important case and will confine immediate comment to a mere indication of one or two salient features. One immediate effect of the decision is to throw open to the public the manufacture of an edible product by the hydrogenation of an oil. Another more widespread result will be from a probable effect on patent law: the recognition of the principle that a product may not be described in terms of a process.

Two Great Americans On Chemical Independence

CHIEF among the founders of our Republic stands ALEXANDER HAMILTON. The governing principle of his policy, of WASHINGTON who supported him, and of the whole Federalist party which followed him, was to establish supreme sovereignty. HAMILTON sought this prime object by threefold means, as is clearly brought out in an excellent appreciation of his life by an admiring Englishman, FREDERICK S. OLIVER. The idea of his financial policy was the welding of the Union, of his foreign policy to confirm independence, and of his commercial policy the development of the estate. Of these, only the last failed of vigorous prosecution and substantial acceptance during his brief lifetime. Indeed the last has been ever at the mercy of logrollers rather than in the hands of statesmen.

HAMILTON's report to the House of Representatives on manufactures urges that "not only the wealth but

the independence and security of a country appear to be materially connected with the prosperity of manufactures. Every nation, with a view to those great objects, ought to endeavor to possess within itself all the essentials of national supply. These comprise the means of subsistence, habitation, clothing and defense.

"The possession of these is necessary to the perfection of the body politic; to the safety as well as to the welfare of the society. The want of either is the want of an important organ of political life and motion; and in the various crises which await a state it must severely feel the effects of any such deficiency. The extreme embarrassments of the United States during the late war, from an incapacity of supplying themselves, are still matters of keen recollection; a future war might be expected to exemplify the mischiefs and dangers of a situation to which that incapacity is still, in too great a degree, applicable, unless changed by timely and vigorous exertion."

By "the late war" HAMILTON referred to a successful war against Great Britain; many of these phrases bear equal application to conditions existing during and after our recent war against Germany. Indeed, HAMILTON stood on fundamentals and saw wide; he viewed the future as a true prophet. He saw a great continent united by miraculous good fortune into one state, of unknown extent, unexplored except for an eastern fringe. His vision was of one great nation, capable of producing within its own wide borders everything that its citizens would require for safety and for comfort. Distant from its neighbors, it might hope to escape from embroilment in their quarrels; dependent upon them solely for some essential, the wars, disasters and policies of strangers would be a constant menace to its prosperity. It is at the mercy, not only of the malice of its rivals, but of the misfortunes of its friends.

A well-balanced domestic establishment and self-sufficiency in essentials is now and perhaps ever will be a question worthy of serious thought and careful action. Witness the following quotation from the message delivered last week to the short session of Congress by President WILSON—whom even the most rabid critic would not accuse of levity or rashness:

"Permit me to emphasize once more the need for action upon certain matters upon which I dwell at some length in my message to the second session of the Sixty-sixth Congress: The necessity, for example, of encouraging the manufacture of dyestuffs and related chemicals; the importance of doing everything possible to promote agricultural production along economic lines, to improve agricultural marketing and to make rural life more attractive and healthful."

Can the Republicans follow HAMILTON's advice and the Democrats follow WILSON's advice to the extent of adopting a sound policy on chemical independence?

Methods of Making Market Prices

NORMALLY the locomotive engineer regulates the speed of his train from moment to moment according to the nature of the roadway. On the one hand he is not supposed to exceed the safe limit and on the other hand he is expected to keep up to the schedule, while the schedule in turn has been made with a view to getting the patrons of the road to their destinations in the shortest time consistent with other influences. It would certainly be a very crude and inefficient method for the engineer to reduce speed only when he felt some of the wheels leaving the track, or to go as slow as he chose until the passengers held an indignation meeting and formally instructed him to go faster.

The manner in which market prices for many commodities are set is not essentially very different from the alternative manner of operating a railroad train suggested above. Prices are held until an accident occurs, by way of somebody cutting the price, and then producers make a fresh stand upon the reduced price until another accident occurs. For the lower limit, there is a law against unfair or destructive competition whereby in certain circumstances legal process could be invoked to prevent a manufacturer selling below his cost.

A practice of artificial price control among manufacturers is regarded as inherently wrong and against public policy. It is contrary to the common law and is in direct violation of a specific statute, the Sherman "anti-trust" act of 1890, enacted to crystallize the common law, prescribe methods of procedure and fix definite punishment for violation.

In the '90s and in the early years of the present century there were various "pools" and "associations" in the finished steel trade. This was brought out by the Government in the recent suit against the Steel Corporation. The court found, in substance, that the procedure was wrong, and cleared the Steel Corporation chiefly on the ground that its participation ceased in 1904. At the present time there are few associations among manufacturers of the ordinary steel mill products, but there are many associations among consumers of those products. These associations claim to be operating wholly within the law, and that the Federal Trade Commission is cognizant of all their actions. A study of market prices, however, shows that in most cases the manufactured goods sold to the public by members of these associations stand at greater percentages above the pre-war prices than do the rolled steel products which are purchased as raw material from the rolled steel industry.

The spirit of some of these associations seems to be that since they have not the power to hold prices absolutely at all times from going below the level affording a fair profit they should get more "when the going is good" in order to make a suitable average in the long run.

While the steel industry is naturally indisposed to criticize its customers, it does not seem entirely fair that the ultimate consumer should pay a larger profit upon one stage of the manufacture than upon another, when the amount of business done by each successive manufacturer is regulated more or less by the price the ultimate consumer pays.

Commodity prices in general, particularly of manufactured goods, are made by a distinctly hit or miss

process. In the case of hits the seller tries to make them as hard as possible, and for the misses there is nothing but to hope that the hurt will not be serious or permanent. Obviously the old law of competition, if it ever was a safe law, is absolutely ineffective to produce prices at all times fair both to producer and to consumer, because "overhead" has become so large a part of manufacturing cost and in competition a manufacturer does better to lose part of his overhead by selling below total cost than to lose it all by closing his factory. The whole thing is very crude and it is a wonder we get along at all.

Adsorption Phenomena as Applied to Vapor Recovery

IT HAS been only in the past year that research on adsorption of vapors by silica and activated charcoal has given any sign of being productive of an industrial conquest. This is largely due to the introduction of poisonous vapors in offensive warfare with the consequent development of the gas mask as the defensive equipment. In the past the phenomenon of adsorption has received a great amount of speculative treatment and comparatively meager qualitative and quantitative study. The factors have long been recognized in terms about equally complex as adsorption itself, such as capillary-equilibrium between the liquid and vapor phases, which in turn can be resolved first into wetting power of the liquid phase and then to intramolecular forces.

It is observed that when a drop of any liquid is placed on any solid surface, the behavior of the drop is dependent on the resultant of three forces: The surface tension of the liquid in equilibrium with its vapor phase, the contact tension between the liquid and solid, and the surface tension of the solid itself. The magnitude of each of these forces is probably a function of density and intramolecular cohesion, from which we may anticipate the high-surface tension of mercury relative to that of water, and explain the familiar globular form of mercury when in contact with lighter chemically-inert materials. Wetting power is of fundamental importance in capillary adsorption phenomena, for it governs the action of Jurin's Law upon which differences in vapor pressure head depend.

Beginning with this issue, the action of silica gel on single vapors will be described. In the near future, the selective adsorption of the intermediate paraffine series from natural gas by activated charcoal will be taken up, showing that equilibrium tends toward saturation with the higher molecular weight liquids, which expel the lighter ones. Water vapor is at once about the most condensible and greatest vapor expeller that is encountered in adsorption work. Needless to say, where it occurs with the vapor to be adsorbed, the adsorption has to be performed in two stages.

The possibilities of fractionation of mixed vapors by selective adsorption are great, but up to the present they do not seem to have been very extensively investigated. Gases have been cooled below their critical temperature, where the liquid-vapor equilibrium phase replaces the gas state, and there appears to be a possibility that an improvement may be made on the refrigeration method of fractionating such mixtures as air into liquid oxygen and nitrogen gas, with a higher yield than can be economically obtained by the older methods.

Is Chemical Warfare Service Being Stifled?

NOT long ago the Surgeon General of the Army published a report on casualties in the World War which brings out clearly the important part played by gas warfare. In view of the recent history of the Chemical Warfare Service it seems well to summarize them once more.

Out of a total of 258,338 casualties, 70,552, or 27.3 per cent, were caused by gas. Of the 266,112 wounds inflicted upon 224,089 Americans admitted to hospitals, 88,980, or 33.4 per cent, were due to gas. Hand grenades were responsible for 1,158 wounds, pistols 257, bayonets 245, airplane bombs 160 and sabers 14.

Less than 2 per cent of the men suffering from gas admitted to hospitals died, while in the case of the 153,537 suffering from all other classes of wounds admitted to hospitals 12,470, or 8.1 per cent, died. Furthermore, during the years 1918 and 1919, tuberculosis was respectively only 70 and 55 per cent as prevalent among gassed men as among those not gassed.

Study of these data convinces one not only that gas warfare is very effective but that it is also one of the most humane methods of waging war. With these facts in mind, consider the present status of the Chemical Warfare Service. Here are the facts:

The Army reorganization act, approved June 4, 1920, provided for the Chemical Warfare Service in the following language:

Sec. 12a, Chemical Warfare Service. There is hereby created a Chemical Warfare Service. The Chemical Warfare Service shall consist of one chief of the Chemical Warfare Service with the rank of Brigadier General, one hundred officers in grades from Colonel to Second Lieutenant, inclusive, and 1,200 enlisted men. The chief of the Chemical Warfare Service under the authority of the Secretary of War shall be charged with the investigation, development, manufacture or procurement and supply to the Army of all smoke and incendiary materials, all toxic gases, and all gas-defense appliances; the research, design and experimentation connected with chemical warfare and its material; and chemical projectile filling plants and proving grounds; the supervision of the training of the Army in chemical warfare, both offensive and defensive, including the necessary schools of instruction; the organization, equipment, training and operation of special gas troops, and such other duties as the President may from time to time prescribe.

With this authorization, what have the War Department officials done?

Shortly after the passage of the Army reorganization bill, the following paragraph set forth the idea of a special board regarding chemical warfare:

That no troops of the Chemical Warfare Service should be assigned within the Army as combat organizations, but that this Service shall carry on research and development. This is a supply service whose product should be utilized when necessary by combat troops of all arms of the line.

Following the publication of the above mentioned paragraph, tables of organization were issued, in which no mention whatever is made of chemical warfare troops in any military organization for peace or war.

No Chemical Warfare officers have been provided for in any other positions in armies, corps or divisions, notwithstanding they were used on the staff of every commanding general in the World War and were provided for under War Department rules carrying out the provisions of the appropriation act of July 11, 1919, which continued the Chemical Warfare Service during the fiscal year 1920.

This means—if, it means anything—that the Army will get no training whatever in chemical warfare.

Apparently to make certain that this training cannot be carried out, a recent decision is that no line officers will be permitted to attend Chemical Warfare Service schools, and that no Chemical Warfare officers will be detailed as instructors in Army service schools or with the National Guard, or in Reserve Officers Training Camps. A tremendous quantity of gas masks and other gas-defense material in the hands of Regular Army divisions in this country and also in the Philippines will soon be without the trained men necessary for their proper care.

Another decision, along the same line is not to allow target practice with chemical ammunition other than smoke except at Edgewood Arsenal or Lakehurst, N. J. One of the reasons given for this action was that gas cannot be fired on ordinary target ranges without objection of civilians near by. This in spite of the demonstrated fact that gas can be used with greater safety on such ranges than high explosive.

Is it the idea to teach the Army that gas is too dangerous to train with in time of peace?

Despite the decision that Chemical Warfare Service should primarily carry on research and development, even this activity has been hampered by such acts as the refusal of permission to construct quarters for high-grade civilians at Edgewood Arsenal. This refusal was rendered notwithstanding the Judge Advocate General sustained the opinion of the chief of the Chemical Warfare Service that there was ample law for the use of money now in the hands of the Chemical Warfare Service for that purpose.

While the total appropriation recommended by the War Department for the year 1922 amounts to about \$700,000,000, a little less than \$4,500,000 is for chemical warfare. Is an organization handling a weapon fifty times as effective as hand grenades, pistols, bayonets, sabers and airplane bombs, all combined, to be starved to death?

That these decisions are largely the opinions of Washington War Department officials only is evident from the many requests made for chemical warfare instruction or chemical warfare troops by commanding generals of divisions, corps areas, departmental areas or service schools outside of Washington. For instance the commanding general of Camp Benning, Ga., has tried for six months to have a company of chemical warfare troops sent there. The chief of infantry has strongly indorsed such request. Needless to say also, the chief of the Chemical Warfare Service has done everything he could to get them sent there, but every request has met with constant refusal.

We repeat the question at the head: "In the light of these facts, can one conclude that the Chemical Warfare Service is being stifled?"

Minerals Separation's Application Again Denied

UPON another page we print a brief abstract of the opinion of the United States Circuit Court of Appeals, which not only fully sustains the District Court in its denial of a petition to find the Miami Copper Co. in contempt for continuing its flotation operations but would seem to add force to what we interpreted as a rebuke from the District Court because of its necessity of speaking twice to be heard.

Readers' Views and Comments

Electric Furnace Refractories

To the Editor of Chemical & Metallurgical Engineering

SIR:—In a recent article in your journal entitled "Electric Furnace Refractories," by A. F. Greaves-Walker,¹ certain statements are made with regard to magnesite which need correction.

The author mentions the two general types of naturally appearing magnesite—namely, crystalline and amorphous, and then proceeds to state that the latter is entirely unsuited for the manufacture of refractories. This statement has been shown, both by laboratory research and actual practice, to be incorrect, although it has occurred from time to time in the literature and has been generally accepted as true up to very recent times.

The truth of this statement was given some apparent substantiation by the general failure of the California amorphous magnesite to yield a satisfactory refractory magnesite and by the great success, as a refractory, of the dead-burned magnesite shipped from Chewelah, Wash., by the Northwest Magnesite Co. But the Northwest Magnesite Co. was the first in the United States to build and operate a plant which produced a true dead-burned magnesite. No such plants have ever existed in California on an extensive scale, and no true dead-burned magnesite has ever been produced in California, except on a small scale. However, this small production has been recognized for some years as a very high-grade refractory material, and it served a valuable purpose during the war as a lining for furnaces producing carbon-free ferro-alloys. Washington magnesite, if calcined by the usual California method, would be worthless as a refractory material. The production of a high-grade refractory magnesite is largely a matter of process and apparatus, and provided the original analysis of the rock is within certain prescribed limits it makes no difference whether it be in crystalline or in the so-called amorphous state, if the proper procedure be followed which is necessary for the production of dead-burned magnesite.

These statements, which are the result of practice, of course proceed from certain underlying facts regarding the nature of magnesite. There is no real distinction between crystalline and so-called amorphous magnesite, except in the size and development of the crystals. (The amorphous is in reality a cryptocrystalline magnesite.) Crystalline magnesite is usually less pure² than the cryptocrystalline, and particularly it usually contains more iron; but there are deposits of cryptocrystalline magnesite in California which contain more iron than the Washington crystalline magnesite, and also some which contain less iron and more lime and silica.

Both crystalline and cryptocrystalline magnesite, when properly calcined at 750 to 800 deg. C., yield amorphous magnesia entirely free from CO₂ gas and of a greater or less degree of purity, according to the constituents of the original rock. Amorphous magnesia, owing to its low specific gravity and its tendency to

shrink at high temperatures, is worthless as a refractory material. If its temperature is raised to 1,550 deg. C. and if 5 to 6 per cent Fe₂O₃ be present and intimately mixed with it, amorphous magnesia is completely transformed to a crystal known as periclase and the resulting product is dense, hard and sintered, and is known as dead-burned magnesite.

These facts disclose that dead-burned magnesite is produced by a heat treatment of CO₂-free amorphous magnesia, whereby periclase is formed, and it makes no difference whence the amorphous magnesia came. Furthermore, the production of dead-burned magnesite is only incidentally connected with the calcining of magnesite. All of the CO₂ can be driven from magnesite without producing a single per cent of periclase, and on the other hand periclase can be produced from amorphous magnesia which never had been in the form of the carbonate. Periclase was never completely formed in California magnesite, and the magnesite was therefore never completely dead burned because the calcined magnesite was never heated as high as 1,550 deg. C., but if it did happen to be heated to this temperature in the process of manufacture, there was not sufficient iron present to initiate the crystallization. The great bulk of California magnesite, therefore, which was shipped in the early days of the industry, was not thoroughly dead burned. It was considered so at that time, however, because dead burning and calcining were confused and it was thought that all that was necessary to accomplish the dead burning of magnesite was to completely drive off the CO₂ gas.

The presence of iron oxide is necessary in making dead-burned magnesite because it catalyzes the transformation of amorphous magnesia to periclase. If iron is not present, this transformation requires a higher temperature than is practical in ordinary commercial furnaces using oil or coal as fuel. Microscopic examinations have demonstrated that iron oxide added to the rock under proper conditions is exactly equivalent in its action to the iron which occurs naturally in the rock.

Consideration of these facts entirely refutes the old and oft-repeated claim which Mr. Walker has again repeated, that Austrian magnesite is a material in a class by itself. No one disputes the fact that it is an excellent refractory material, but we now know both from practice and laboratory research that we are producing the same material in America, and the best proof of this statement is that American metallurgical industries, including those employing electric furnaces, have been operating without hindrance in so far as refractories are concerned for over two years, using almost entirely American magnesite. Inquiries which have been made from time to time of those operating open-hearth furnaces and electric furnaces establish the fact that American magnesite is giving the highest satisfaction and is considered the equivalent, in every particular, of Austrian magnesite.

Northwest Magnesite Co.,
San Francisco, Cal.

Action of Steam and Gases on Yields of Ammonia From Carbonization of Oil Shales and Coal

Discussion of the Various Factors and Physicochemical Laws Affecting the Ammonia Equilibrium—Synthetic Action of Steam and Hydrogen—Removing Action of Inert Gases From Decomposition Zone

BY ARTHUR J. FRANKS

THE importance of nitrogen to the industrial, agricultural and military progress of nations has stimulated prolific research in methods of production, and especially conservation of this resource. In certain localities the principal source of nitrogen lies in the byproduct ammonium compounds obtained from the carbonization of coal and oil shales; and activities in the direction of byproduct recovery are continually expanding in the great countries of the world.

The steaming of retorts has accelerated this advance toward the conservation of the ammonia yield, and steaming practice has been under investigation for nearly a century with the view of magnifying its usefulness. Yet when one refers to the literature for the reactions involved, or the *modus operandi* of the steaming process, only very meager data, generally from plant practice (and sometimes of questionable accuracy), are found, together with the admission of our ignorance of the principles involved, or, what is less satisfactory, dubious hypotheses which are unable to withstand the light of our present knowledge.

PRINCIPAL FACTORS INVOLVED IN AMMONIA EQUILIBRIUM

As ammonia decomposes at temperatures below those of the ordinary coal or oil shale retort, how are we to explain the yield which is nevertheless produced, as practice shows? Ignorance of the laws involved has given rise to many controversies. Some have even gone so far as to state that "there is something unsound in your theory, which is not a safe guide to follow." It is generally not the theory which is at fault, but its misapplication to conditions under which the theory cannot be expected to hold. It will be the purpose of this paper to consider these various physical conditions, in connection with the effect of steam and inert gases on the ammonia yield, and to interpret the phenomena that attend in the light of our physicochemical laws.

It is first necessary to consider all the pertinent facts involved in the ammonia equilibrium¹

as well as the general laws that govern:

At or above 780 deg. C., and at atmospheric pressure, the equilibrium is displaced completely to the right (in an iron tube and in the absence of catalysts)—that is, the decomposition is complete.²

The dissociation is endothermal, hence the equilibrium is shifted toward the right as the temperature rises.

The decomposition proceeds with an increase in volume and is therefore favored by the reduction of pressure.

The introduction of inert gases at constant volume has no effect on the equilibrium.

Dilution with inert gases attended with an increase in volume displaces the equilibrium to the right, or increases the dissociation.

Increasing the concentrations (and hence the partial pressures) of either the N₂ or H₂, or decreasing that of the NH₃, will shift the equilibrium to the left.

The rate of the reaction to the left is proportional to the product of the concentrations of the decomposition products, with a constant thermodynamic environment.

Catalysts have a very pronounced action on the temperatures of decomposition and especially upon the reaction rate, which is very slow.

DECOMPOSITION TEMPERATURE

According to the experiments of Ramsay and Young pure ammonia is completely decomposed at 780 deg. under the conditions given. But it must be remembered that these conditions do not obtain in practice during the retorting of oil shale or coal, for equilibrium is not attained, and that temperature is the controlling factor in determining the degree of dissociation *only when complete equilibrium is reached*. Unless the system is in equilibrium we have no means of predicting what the dissociation constant will be, but the dissociation will, of course, be greatly decreased.

Other factors, not considered in the observations of Ramsay and Young, enter during the carbonization process to further complicate the thermodynamic environment. Hence, for our present purpose, the results of those experiments are of little value, and become less and less applicable as the number of variables in the system increases.

DISSOCIATION IS ENDOTHERMAL

From the endothermicity of the reaction and the principle of Le Chatelier it is evident that heat aids the dissociation of ammonia into its elements, and that the higher the temperature the greater is the decomposition. The magnitude of this dissociation by heat is, of course, greatest at equilibrium, but it proceeds at all times to a greater or less degree, depending upon the nature and number of other

TABLE I. EFFECT OF TEMPERATURE ON NH₃ FORMATION

T, Abs. C.	deg. C.		
973	700	0.000174	0.000183
1,073	800	0.000088	0.000089

1,273	1,000	0.000032	0.000029

variables in the system. Table I demonstrates the effect of temperature rise on the amount of ammonia found in an equilibrium mixture of 75 per cent hydrogen and 25 per cent nitrogen at one atmosphere pressure, the values being taken from the observations of Jost.³

¹Jellinek, "Physikalische Chemie der homogenen und heterogenen Gasreaktionen," p. 682.

²Ramsay and Young, *J. Chem. Soc.*, vol. 45, pp. 88-93; 1884.

³*Z. anorg. Chem.*, vol. 57, p. 425 (1908).

In this table X is the volume of NH_3 per unit volume of mixture as observed, and X_c the calculated results from Nernst's form of the reaction isochor.*

The influence of the presence of other gases in the mixture together with the lack of equilibrium would effect a tremendous difference in the above figures, but the actual results under such changed conditions could hardly be predicted except within the limits of pure speculation. This is clear from results of experience in gas manufacture. If the dissociation proceeded at the rate given for the temperatures in Table 1 no ammonia would ever be found in the gas, as it would all be decomposed at 800 to 900 deg., the temperature which practice demonstrates to be the most favorable^b for the greatest ammonia yield.^c The explanation for such apparently contrary phenomena can be found only in the absence of equilibrium and the presence of gases other than ammonia, especially hydrogen. The manner in which these conditions produce the above-mentioned results will be evident from the discussion in another part of this paper.

EFFECT OF PRESSURE AND VOLUME

Since the dissociation proceeds with a volume increase, pressure will act to reverse the reaction and shift the equilibrium to the left according to the Le Chatelier principle. Conversely, a reduced pressure favors the disintegration of the ammonia molecule. Now this action of pressure is not affected by the presence of inert gases (so long as the partial pressure of the ammonia in the gas mixture is unaltered), and tends to manifest itself whether the system is in equilibrium or not. Unfortunately, however, carbonization is generally carried out at pressures but slightly greater than atmospheric; hence we can look to no aid from this source to explain away our anomaly, and the pressure factor may be hereinafter neglected.

EFFECT OF INERT GASES AT CONSTANT VOLUME

It is at once apparent from Dalton's law that dilution of the reaction mixture with indifferent gases at *constant volume* would have no effect upon the dissociation, since the partial pressures of the reacting components would not be so changed. But the introduction of steam and inert gases (such as are evolved during the carbonization) cannot be considered as taking place without a volume change, as this is accomplished at practically *constant pressure*, and the gas volume is thereby *increased*. This gives rise to the condition considered under the next head.

EFFECT OF INERT GASES WITH INCREASE IN VOLUME

From the principle mentioned above it would be logically supposed that dilution attended with an increase in volume would increase the dissociation. This is always the case where the decomposition is accompanied by a volume increase or where the products of the dissociation occupy a greater volume than the undissociated substance, since the dilution results in a lowering of the partial pressures of the components concerned in the reaction.

The mechanism of the diluting phenomenon will be clearer from a study of the following example. Assume an ammonia equilibrium within a constant thermo-

dynamic environment, the temperature being that at which the gases are present in the molal concentrations given in equation 1 for ease in calculation, and the pressure being six atmospheres. According to the mass law there is a definite ratio at all times between the amounts of each component of this mixture, from which is obtained the dissociation constant K , or from equation 1,

$$\frac{[N_2][H_2]^3}{[NH_3]^2} = K; \quad (2)$$

where $[]$ signify the volume concentration of the component in question. Since the concentrations of the constituents are proportional to their respective partial pressures, or to the number of mols present, equation 2 may also be written:

$$\frac{P_{N_2} (P_{H_2})^3}{(P_{NH_3})^2} = K_p = \frac{1 (3)^3}{(2)^2} = 6.75. \quad (3)$$

Now assume a dilution to occur without a change in pressure, so that the volume is now two times the original. The partial pressures of the ammonia, hydrogen and nitrogen are consequently reduced to one-half their former values and the equation becomes:

$$\frac{0.5 (1.5)^3}{(1)^2 X^2} = \frac{1.6875}{X^2} = 6.75. \quad (4)$$

Since K_p is a constant the value of X becomes 1, which means that the equilibrium will shift until the concentration (and hence the partial pressure) of the ammonia becomes one-fourth of its original value. Thus the dissociation would have been increased fourfold by a dilution with an equal volume of an inert gas.

In spite of the above facts and the deductions therefrom it is known from practice that the yield of ammonia is increased by dilution instead of decreased, as would be expected. This is simply accounted for by the fact that part of the diluting gas is hydrogen, which is not inert, and that the mass law is valid only at equilibrium; and since the conditions that exist are far from such a state the law does not pretend to hold. However, the *tendency* toward dissociation of course exists, but is more than completely overcome by the relatively high velocity of the gases through the reaction zone, which, due to the slow rate of reaction to the right (in equation 1), causes the ammonia molecules to be removed before the predatory actions of temperature and dilution have had an opportunity to accomplish much of their evil work, and by the presence of much hydrogen, which operates against the decomposition.

SHIFTING THE EQUILIBRIUM

Obviously, this is again an application of the mass law. If the concentrations of the nitrogen or hydrogen exceed those required by the equation, and the presence of an excess of one or both of these elements can be accounted for in ordinary carbonization practice, then we will have another part of our explanation for the conservation of the ammonia yield. The hydrogen has an especially potent action on the shifting of the equilibrium to the left, for, from equation 3, the amount of ammonia varies directly as the *cube* of the hydrogen partial pressure or concentration, assuming a constant thermodynamic environment. For example, increasing the partial pressure (at constant temperature) of the hydrogen from three to six in equation 3 causes a shift in the equilibrium until the ammonia concentra-

*² *Elektrochem.* (1910), p. 100.

^bLewes, *Carbonization of Coal*, p. 259.

^cIn an ordinary horizontal retort and without steam.

tion becomes *eight times* the original value, as the calculations demonstrate:

$$K_p = 6.75 = \frac{(1)(6)^2}{X(2)^2} = \frac{54}{X}; \text{ or } X = 8. \quad (5)$$

Following the same reasoning, it is seen that the nitrogen will have less effect on the equilibrium, the ammonia varying directly with the nitrogen concentration. Here again it must be remembered that while the above phenomena occur to the extent shown only at equilibrium, the tendency is nevertheless in the direction indicated.

In order to apply the results of these observations to the retorting of oil shale or coal, the source of the nitrogen and hydrogen and their relative approximate concentrations must be determined. This must be accomplished for four different sets of conditions:

- A. Retorting at low temperatures without steam.
- B. Retorting at low temperatures with steam.
- C. Retorting at high temperatures without steam.
- D. Retorting at high temperatures with steam.

RETORTING AT LOW TEMPERATURES WITHOUT STEAM

Research on carbonization¹ has established the fact that at low temperatures (not above 500 deg. C.) ammonia is a primary decomposition product and is formed directly from the nitrogen compounds existing in the material distilled. Such being the case, the influence of an excess of ammonia decomposition products would result in the tendency to prevent the equilibrium from going toward the right, since the combination of hydrogen with nitrogen is very slow and the reaction to the left would therefore be practically *nil* under the conditions that obtain.

The ammonia in the gases from the low temperature carbonization (at about 500 deg. C.) of oil shales or coal seldom exceeds 5 per cent by volume.² The hydrogen in the coal gas, on the other hand, will vary between 25 and 30 per cent,³ and in the oil-shale gases it will be between 20 and 25 per cent.⁴ The percentage of nitrogen is quite low in good gas, and as it has relatively little effect on the decomposition it need hardly be considered. The predominance of hydrogen over ammonia at these temperatures is therefore apparent, as well as the result.

RETORTING AT LOW TEMPERATURES WITH STEAM

At the low temperatures here considered the dissociation of steam into its elements is almost zero, as Table II⁵ shows.

Also, the amount of hydrogen produced from the ac-

TABLE II DISSOCIATION OF WATER VAPOR AT ATMOSPHERIC PRESSURE

Temperature, Deg. Abs.	Percentage Dissociation
1,000	0.00003
1,500	0.022
2,000	0.59
2,500	3.98

tion of steam on carbon is relatively small up to 500 deg. C.⁶ Hence the steam can be considered here to act mainly as a mechanical agent which serves to prevent the decomposition of the ammonia by removing it from the zone of reaction and thus forestalling equilibrium. The hydrogen formed during the carbonization

has, of course, the same action as in retorting at low temperatures without steam, but to a lesser degree, due to the lowering of its partial pressure by the steam. Any inert gas would have practically the same effect as the steam under these conditions.

RETORTING AT HIGH TEMPERATURES WITHOUT STEAM

The same general considerations governing retorting at low temperatures without steam hold at high temperatures of carbonization (about 800 to 900 deg. C.), except that the percentage of hydrogen in the gases is much greater, being usually from 45 to 55 per cent.⁷ Hence its protective action will be much increased. But on the other hand, the destructive tendencies of the elevated temperature will also be more pronounced; yet its influence is mitigated by the slow velocity of reaction (equation 1) to the right. It is evident that the resultant of these two opposing forces could not be predicted with any precision because it is dependent, under the given conditions of temperature and pressure, mainly upon the velocity of the gases through the zone of reaction. So the problem would have to be worked out empirically for any given set of conditions.

In connection with the action of hydrogen on the yield of ammonia from coal at high temperatures, the work of Tervet⁸ will be of interest. His experiments showed that a stream of hydrogen, introduced at red heat into a mass of coal from which the rich hydrocarbon gases had just been distilled, caused the formation of ammonia in considerable quantity. These experiments were carried out with charges of 100 g. of coal in a 4-in. iron tube, the temperatures running up to almost 1,000 deg. C. The higher the temperature and the greater the velocity of the hydrogen through the tube the greater was the amount of ammonia produced.

Tervet's explanation of the action of the hydrogen is that "the nitrogen existing in coke can be liberated in the form of ammonia, it being only necessary to bring the compound into a state of strain by subjecting it to the superior affinity which exists between the combined nitrogen in the coke and the free hydrogen at a particular temperature and in a predominating atmosphere, which shall prevent it from subsequent decomposition." Tervet made experiments with other gases also, and found that nitrogen, methane and carbon dioxide had no action, and carbon monoxide very little, but that coke which had been submitted for hours to the action of these gases, which had failed to wash out any trace of ammonia, directly a stream of hydrogen was passed through it yielded ammonia in abundance.

If any ammonia had been produced during the carbonization at these high temperatures as a *primary* decomposition product, then some of it should have been found in all the wash gases, at least at high velocities through the tube. Its absence permits only one conclusion that the ammonia was synthesized from the nitrogen in the coke and the hydrogen, the presence of the enormous excess of the latter preventing the reversal of the ammonia reaction toward the right and increasing the velocity of the reaction to the left. The mechanism of this phenomenon will be elucidated later.

RETORTING AT HIGH TEMPERATURES WITH STEAM

The use of steam during high-temperature carbonization introduces a number of complications, since it can no longer be assumed to be inert. Under the condi-

tions that obtain we have to deal with the system C, H₂O, CO, CO₂, H₂, and hydrocarbon vapors, in addition to the system represented by the ammonia equilibrium. The reactions and possible side reactions involved are quite numerous:

The main reaction is represented by equation 6, but the others also occur to a greater or less extent, depending upon the thermodynamic environment. The oxygen is not included in the system, because it is always in combination with either the hydrogen or carbon; and the extent to which it combines with one or the other depends also entirely upon the thermodynamic environment.

The reason for introducing the above equations into our considerations is that they must all be studied in order to ascertain the amount of free hydrogen which may be expected to be present in the system under a given set of conditions, since this seems to be the primary factor in determining the progress of the ammonia decomposition and association reactions. As the hydrocarbon vapors are practically all evolved during the first part of the carbonization when the temperature of the material being distilled is low, they may be dropped from the system at this point. The carbon dioxide and excess of undecomposed steam have no action, and the carbon monoxide practically none, on the formation of ammonia, but act merely as diluents and mechanical agents for removing the ammonia molecules from the zone of reaction before decomposition can make material progress. Only the hydrogen is left then for consideration here.

At high temperatures hydrogen has the effect noted in retorting at high temperatures without steam, but to a much greater degree due to the increased amount present, and also the synthetic action studied by Tervet.¹¹ An idea of the amount of hydrogen formed by the action of steam on coke at various temperatures may be obtained from Table III.¹²

The amounts of the various gases are expressed in volume per cents, and the velocity, *V*, in liters per second.

It is evident from the table that at high temperatures the steam is almost entirely decomposed by the carbon

TABLE III. CARBON WATER REACTION AT VARIOUS TEMPERATURES

Temp., Deg. C.	H ₂	CO	CO ₂	H ₂ O	<i>V</i>
674	8.4	0.6	3.8	87.1	0.9

1,125	50.7	48.3	0.6	0.3	11.3

according to equation 6, and that the side reactions occur only to a negligible degree. The high percentages of hydrogen are also to be noted. During the earlier part of the carbonization hydrogen is also produced in considerable amounts, and its action at that stage would

be mainly in the direction of depressing the decomposition of the ammonia. As the temperature of the mass of coal or oil shale rises, more and more hydrogen is produced from the steam, and the Tervet reaction begins, it being more and more prominent as the amount of hydrogen and the temperature increase. Here again the high velocity of the gases through the retort and the great excess of hydrogen produced from the use of steam, together with the slow rate of decomposition of ammonia, account for its integrity on the one hand and its partial synthesis on the other.

RATE OF REACTION PROPORTIONAL TO PRODUCT OF DECOMPOSITION PRODUCTS

Experiments show that in gaseous systems within a constant thermodynamic environment the rate of a chemical reaction is proportional to the product of the concentrations of the reacting molecular species, each concentration being raised to a power equal to the number of molecules of the corresponding molecular species entering into the reaction, as indicated by the equation expressing the reaction as it actually occurs. This is Guldberg and Waage's law¹³ of chemical mass action as applied to rates of reaction. Where the reaction is reversible, as is the case with ammonia, then the resultant reaction rate at any time is the algebraic difference between the two opposing rates, the sign being considered positive when this difference is in the direction of combination, and negative when toward dissociation. These facts may be represented very clearly by the use of the calculus in the following equations:

$$-\frac{d[NH_3]}{dt} = K[NH_3]^2 \quad (12)$$

$$\frac{d[H_2]}{dt} = \frac{d[N_2]}{dt} = k[H_2]^3[N_2] \quad (13)$$

$$\frac{d[NH_3]}{dt} = \frac{d[NH_3]}{dt} - \frac{d[H_2]}{dt} = K[NH_3]^2 - k[H_2]^3[N_2] \quad (14)$$

Here the square brackets represent the concentrations at the time *t* of the molecular species in question, expressed as equivalents per liter. The derivative of any concentration with respect to the time represents, of course, the rate of change of that particular concentration, and as the concentration progressively diminishes during a decomposition the sign of the differential is negative. However, as soon as the rate of combination exceeds that of decomposition, the sign changes to positive. This is evident from equation 14, which expresses the resultant rate of reaction.

A study of this equation also renders obvious the fact that an increase in the concentration of the hydrogen should cause a tremendous increase in the reaction rate (and this in the positive direction) since it is proportional to the cube of the hydrogen concentration, and that the rate of the decomposition¹⁴ (or the reaction in the negative direction) will be comparatively very small because the concentration of the ammonia in the gases is exceedingly low, being less than 2 and usually not over 1 per cent by volume in carbonization at high temperatures with a liberal use of steam. Thus the net result, or the resultant positive rate of reaction, should be relatively high. These considerations furnish the most plausible explanation for the Tervet reaction and the production of additional ammonia by the use

of steam during carbonization, when taken in connection with the high velocities of the gases through the zone of reaction and the natural slow rate of decomposition of the ammonia molecule.

CATALYTIC ACTION

Mention has already been made of the fact that the decomposition of ammonia into its elements is very slow, as is often the case with endothermic reactions. This has been shown experimentally by Perman and Atkinson,²⁰ and by Bodenstein and Kranendieck,²¹ who have investigated the rate of isothermal dissociation at different temperatures and found that the rate of reaction is greatly affected by catalysts, which both accelerate the decomposition and lower the temperature of dissociation. It is the opinion of Bodenstein and Kranendieck that the reaction goes on entirely in the surface of the containing vessel, and not in the gaseous phase. The conclusions of Ramsay and Young²¹ point in the same direction.

Table IV shows Bodenstein and Kranendieck's²² determinations of the rate of decomposition of ammonia in a quartz tube at 780 and 880 deg. C. and at different initial pressures, by the manometric method. The

greater rates obtained with the higher initial ammonia concentrations are noticeable at the lower, and very marked at the higher temperature, as would be predicted from the mass law.

The time expressed in minutes and the amount of N₂ + 3H₂ formed is expressed in mm. P₁ is the initial pressure in mm. of the ammonia at the beginning of the experiment, and dx/dt represents the rate of change in the ammonia concentration, or the rate of decomposition.

Analogous results were obtained by Perman and Atkinson,²³ who studied the dissociation in a porcelain vessel at temperatures from 677 to 1,111 deg. C. They showed, however, that a thin deposit of platinum black on the surface of the vessel caused a marked increase in the rate of decomposition, as well as a lowering in the temperature of decomposition. Iron had also a pronounced effect. In the absence of catalysts and at high temperature the reaction is shown to proceed as one of the first order, or

The union of the atoms to form molecules is probably so quick that it is negligible when compared with the rate

of decomposition of the ammonia molecule. This is similar to the decomposition of phosphine,²⁴ which has recently been shown to be a monomolecular reaction. The experiments at lower temperatures (about 800 deg.) as well as Bodenstein and Kranendieck's²⁵ work at these temperatures furnish definite evidence that the reaction is of neither the first nor the second order, since the values for the dissociation constant fluctuate too widely from that of a true constant. But this is to be expected when it is recalled that the walls of the retaining vessel exert a catalytic action on the dissociation rate. The curves of Perman and Atkinson²⁶ illustrate this point beautifully.

Bodenstein and Kranendieck²⁷ investigated also the rate of decomposition of ammonia in the presence of an almost equal concentration of its dissociation products. The results of this work indicate that the concentration of the ammonia in the mixture is of greater importance than that of the hydrogen and nitrogen, the decomposition rate being faster with higher ammonia concentrations, as would be predicted from the mass law. The hydrogen and nitrogen do not have the effect which would be expected. However, the deviations from the theory are quite satisfactorily explained in their paper on the basis of catalytic action, and need not be considered here.

In substantiation of the deductions already drawn from the works of a number of capable investigators, and the applications made thereof, the conclusions from the experiments of Ramsay and Young²⁸ on the decomposition of ammonia may be briefly reviewed. They point out that this decomposition begins at about 500 deg. C., but is very small at that temperature, and that the magnitude of the dissociation depends not so much upon the degree of heat as it does upon the rate of gas flow through the reaction zone and the nature and extent of surface with which the gases come in contact during their passage through this zone. These experimental facts, formerly opaque and obtained at a time when much of our present theory and knowledge was lacking, can now be applied to carbonization practice through the medium of our more recent knowledge of gas kinetics. The demonstration of this harmony between theory and practice is ever gratifying.

SLOW DISSOCIATION RATE

Application of the principles discussed herein to the explanation of the action of steam and inert gases on the ammonia yield during carbonization leads to the general deductions that at low temperatures the steam and gases act both to prevent dissociation of the NH₃ molecules by their presence and to remove them mechanically before material decomposition occurs. At high temperatures steam has also a synthetic action due to the production of large quantities of nascent hydrogen through its reaction with the hot coke and the union with some of the nitrogen contained therein to form new ammonia. The low percentage of this substance and the high per cent of hydrogen in the gases operate to quicken the rate of reaction to the left (equation 1) and, what is of more importance, to depress the rate of decomposition, which has been shown to be very slow. Although the depressing effect of the

hydrogen on the dissociation does not appear to be as great in the few cited cases as would be expected from theoretical considerations, its influence must be felt, since it is present in the gas mixture in amounts twenty-five to fifty times greater than that of ammonia. However, the very slow dissociation rate to the right (equation 1) is the real key to our exposition.

In concluding what may sometimes appear as unnecessarily detailed as well as irrelevant considerations, the author takes the further liberty of emphasizing a few general facts. In dealing with systems that contain such hosts of variables as do the present ones it must be remembered that any knowledge, however remote, which sheds even a tiny ray of light upon the subject is to be accepted gratefully and applied judiciously. There is no doubt that precise results could never be obtained for such cases as those discussed herein except by purely empirical experimentation with a given set of rigid conditions; nor does this paper make any attempt in this direction. The purpose is rather to assemble our pertinent knowledge with the view of arriving at certain definite generalizations and applying these to the elucidation and orientation of what before was to many a confusion of diverse and vacuous facts. If even a partial fulfillment of this purpose obtains, then the author will indeed be satisfied.

Production of Yacca Gum in South Australia

Prior to the war the gathering and shipping abroad of South Australian yacca gum was an important industry on Kangaroo Island, just off the south coast of South Australia, reports Consul H. P. Starrett, of Adelaide. As Germany was the largest user of this product, the industry was suspended during the first years of the war, and not until use had been found for it in the United Kingdom and in America during the latter part of 1916 did the production revive. In 1919 more than 10,000 tons was gathered, and as the Australian consumption is small the greater part of the output was shipped to Great Britain and to the United States. It is believed that further experiments in the use of this valuable product may develop a larger scope for its utilization and thus encourage the expansion of the industry at Kangaroo Island.

USES—CHEMICAL REACTIONS

Before the war nearly two-thirds of the Australian output was bought by German firms. Local dealers have never been able to discover what use the Germans put it to, but it is believed that it was used in the manufacture of furniture polish and lacquer for metal ware. It should not be overlooked, however, that the product contains a high percentage of picric acid on nitration and it is not unlikely that it was also used by the Germans in the manufacture of explosives—a use to which it was put by the Allies in 1917 and 1918.

The gum from the species *Xanthorrhoea hastilis* is, of course, one of the oldest known sources of picric acid, yielding about 15 per cent by treating the gum with strong nitric acid. The gum has also been used in the manufacture of dyes. To quote a technical report on the subject: "The high yield of picric acid on nitration and of paraoxybenzoic on alkaline fusion indicates a chemical constitution for the resin of an oxygenated benzene derivative, and among such derivatives are numerous fine chemicals in daily use—viz., photographic

SUMMARY

The various factors and general laws that affect the ammonia equilibrium have been pointed out and each discussed in detail in connection with the experiments and conclusions of previous investigators.

The information so obtained has been applied to the exposition of the action of steam and inert gases on the yield of ammonia from the carbonization of oil shales and coal.

The integrity of the ammonia molecule at high temperatures and under the other conditions that obtain in retorting is explained by its very slow rate of dissociation, and the remoteness from equilibrium, a condition which is brought about by the presence of steam and inert gases, these removing the ammonia before decomposition can make any marked headway.

The steam is shown to have a synthetic action at high temperatures, and the *modus operandi* of the synthesis of ammonia from the nitrogen contained in the coke is elucidated.

The author takes this opportunity to express his profound gratitude to Dr. S. C. Lind for his many valuable suggestions and criticisms, and for his kindly aid which was always so gladly given.

Colorado School of Mines
Golden, Col.

developers and material used in the preparation of synthetic dyestuffs. The resin is also said to be of considerable importance in the manufacture of linoleum."

Experiments have shown that the gum is soluble in alcohol but insoluble in turpentine, linseed oil, benzene, molten paraffine, and hydrocarbon solvents generally. It dissolves readily in aqueous solutions of caustic alkalis to deep red solutions and, on the addition of acids, is reprecipitated more or less completely as a flocculent dull yellow precipitate. The gum is partly soluble in cold strong sulphuric acid to a deep red solution; on dilution of the sulphuric acid solution and cleaning, the brownish red solid separates. When filtered and freed from the sulphuric acid, this solid dissolves in water and is reprecipitated from its aqueous solution by the addition of a little sulphuric acid.

DESTINATIONS OF EXPORTS

The following table shows the amounts and values of the exports of yacca gum from the State of South Australia for the calendar year 1913 and the fiscal years (ended March 31) 1917-18 and 1918-19. The values have been reduced to American currency at the rate of \$4 to the pound sterling:

Destination	1913 Hundred- weight	Value	1917-18 Hundred- weight	Value	1918-19 Hundred- weight	Value
United Kingdom.....	5,234	\$5,536	5,603	\$12,648	7,022	\$9,836
United States.....	600	600	2,004	2,404	651	848
Germany.....	14,100	12,484
France.....	1,212	1,540
Belgium.....	392	360
Netherlands.....	105	88
Total.....	21,643	\$20,608	7,607	\$15,052	7,673	\$9,684

The exports of yacca gum to the United States as declared at the consular office during the calendar years 1917, 1918 and 1919 were as follows: 1917, 2,979 hundredweight, valued at \$4,977; 1918, none; and 1919, 7,600 hundredweight, valued at \$37,970.

The market price in the city for yacca gum varies from \$36 to \$44 per long ton. Freight, insurance and handling charges amount to about \$48 per long ton.

Adsorption by Silica Gel*—I

Basic Facts and Observations on Adsorption of Vapors by Silica Gel—Partial Vapor Pressure and Liquid Volume Relationships in Capillary Equilibria at Different Temperatures—Data on Sulphur Dioxide

By E. B. MILLER

THE adsorption of vapors by certain porous bodies such as charcoal, kieselguhr, etc., has long been a matter of common knowledge. It was soon found that the retention by such adsorbents was not related to the chemical composition of the substance adsorbed, but was in some way connected with the ease of condensation of the adsorbed vapor. A rough parallelism was noted between adsorption and the boiling point of the vapor when condensed to a liquid.

Much of the uncertainty and inaccuracy of the early adsorption work was due to the difficulty of preparing adsorbents of constant properties. When it was found that adsorbents could be prepared from certain colloidal solutions in an easily reproducible manner it then became possible to study the phenomenon of adsorption with some degree of certainty. Furthermore, when it was found that these latter adsorbents possessed the power of adsorption equal if not superior to that exhibited by adsorbent charcoal the experimental study was made comparatively simple.

Silica gel, prepared from the coagulation of a colloidal solution of silicic acid, is such an adsorbent, and in many respects is an ideal substance for the study of adsorption. It is easily made under conditions that may be reproduced with considerable exactness. It is prepared from inexpensive raw materials, water glass, and either hydrochloric or sulphuric acid. Chemically, it is most inert and is therefore stable in air even at high temperatures.

The adsorption of a number of vapors by silica gel has been studied at different temperatures.

From the results of such experiments it has been possible to discover the factors that are of importance in determining the extent of adsorption.

ADSORPTION DEPENDENT ON VAPOR PRESSURE

It was found that vapors of liquids of a high boiling point were more strongly adsorbed than vapors from a liquid of a low boiling point. Furthermore, adsorption decreased with increasing temperatures. Also, the greater the partial pressure of vapor being adsorbed the greater was the extent of the adsorption. All these facts suggested the idea of condensation of the vapor in the adsorbent. Pursuing this thought, we selected as a measure of the ease of condensation the ratio of the pressure of the vapor in equilibrium with the adsorbent to the vapor pressure of the liquid at the temperature of adsorption. This ratio is herein designated as the "corresponding" pressure. It was soon established that vapors of high corresponding pressure were more strongly adsorbed than those of lower corresponding pressure. The relationship, while qualitatively true, did not correctly represent the phenomena quantitatively.

It was then noted that when the corresponding pressure equaled unity—i.e., when adsorption was measured at the vapor pressure of the liquid, the volumes of the adsorbed liquid were in all cases the same. In other words, it is advantageous, inasmuch as it tends toward simplicity, to express adsorption in terms of volume of adsorbed liquid rather than in weight. The volume of adsorbed liquid was obtained by dividing the weight of the substance adsorbed by the density of the liquid at the temperature of adsorption.

This simple relationship was found to be true only in the case of measurements carried out at a corresponding pressure of unity. At lower corresponding pressures the volume of the adsorbed liquid was not the same at the same corresponding pressure. This discrepancy was attributed to the fact that the condensed liquid under corresponding pressures less than unity had a density smaller than the normal density. Furthermore, the greater the compressibility of the liquid the greater was the deviation of the density of the liquid in the adsorbent from the normal density. By taking these additional facts into consideration all of our experimental observations were quantitatively brought into complete harmony. We are therefore in position to say that the factors influencing adsorption are the corresponding pressure, and the compressibility of the adsorbed liquid.

We have yet to consider the properties of the adsorbent that determine its activity. Inasmuch as the chemical nature of the latter apparently is of no moment, we are forced again to a consideration of a physical property. All adsorbents are porous, and the internal volume is large and composed of exceedingly fine pores. Furthermore, capillarity tells us that a liquid in a small tube possesses a lower vapor pressure than the normal vapor pressure. In other words, it is easier to condense a vapor into a small capillary than on to a level surface. We have therefore in the above all that is necessary to characterize an adsorbent. It must possess as large an internal volume as possible and this volume must be made up of spaces of minimum dimension.

PARTIAL PRESSURE

When we consider silica gel as an adsorbent for the vapor of a liquid at a given temperature, we have to take into account two things: (1) the partial pressure or concentration of the vapor to be adsorbed; and (2) its vapor pressure at the temperature of adsorption. Denoting the partial pressure by P and the vapor pressure by P_0 , we may define the "corresponding

pressure" by the quotient $\frac{P}{P_0}$. It has been found experimentally that the amount of a particular vapor adsorbed

increases with increasing value of the ratio $\frac{P}{P_0}$. Now for

*Paper presented before the American Institute of Chemical Engineers, Montreal, June 28, 1920.

at a given partial pressure, the value of $\frac{P}{P_0}$ increases with decreasing temperature, and for a given temperature, the ratio $\frac{P}{P_0}$ increases with the increase of partial pressure. Hence in practice, we have better adsorption the lower the temperature and the greater the concentration of the vapor to be adsorbed. Maximum adsorption, at a given temperature, will take place when $\frac{P}{P_0}$ has its maximum value, which is unity.

Let us consider a few examples. We may adsorb water vapor at 30 deg. C. from air saturated at 30 deg. C. Under these conditions, $P = P_0 = 30$ mm., and the gel will take up an amount of water corresponding to 25 to 27 per cent of its own weight.

If we consider a similar mixture of sulphur dioxide and air at 30 deg. C.—that is, a mixture in which the partial pressure of sulphur dioxide is 30 mm. (which corresponds to about 4 per cent by volume)—the ratio $\frac{P}{P_0}$ is much smaller than in the case of water, due to the greater vapor pressure of sulphur dioxide. From such a mixture the gel takes up sulphur dioxide to about 6 per cent of its own weight.

If we use a mixture of carbon dioxide and air of the same concentration as above, the value of $\frac{P}{P_0}$ at 30 deg. C. is quite small and only a slight amount of carbon dioxide will be adsorbed.

TEMPERATURE AND CONCENTRATION EFFECT

From a mixture of sulphur dioxide and air containing 4 per cent by volume of sulphur dioxide (partial pressure about 30 mm.), the gel takes up 3, 6, 8.2 and 11.1 per cent sulphur dioxide by weight at 40, 30, 20 and 10 deg. C., respectively. The effect of concentration may be illustrated by the following: Working at 30 deg. C., the gel takes up 2.3, 6, 7.1 and 8 per cent

FIG. 1. ADSORPTION OF SO_2 IN C.C. AT 0, 30, 40 AND 100 DEG. C.

by weight of sulphur dioxide from mixtures containing 1, 4, 6 and 8 per cent, respectively.

Inasmuch as the adsorptive power of silica gel does not depend upon any specific chemical action, but rather upon the physical properties of the vapor to be adsorbed, it may be used successfully at ordinary temperatures and atmospheric pressure to remove from air the vapors of any liquid mixed with air in any proportions, provided the liquid boils, under atmospheric pressure, above -10 deg. C. We must exclude, of course, any vapor which like hydrofluoric acid attacks silica.

From what has been said it will be obvious that lower boiling liquids may also be adsorbed, but it would hardly be practicable to do so efficiently at the ordinary temperature. The so-called permanent gases may be adsorbed at temperatures below their critical points, in their vapor phases, and it is quite likely that such a

FIG. 2. ADSORPTION OF SO_2 IN PER CENT OF GEL WEIGHT

problem as the fractionation of liquid air into oxygen and nitrogen would be made easier by the use of silica gel.

From what was said above in the discussion of corresponding pressure the obvious procedure to follow in order to recover the adsorbed material consists in two steps: (1) raise the temperature, and (2) decrease the partial pressure of the vapor over the gel by evacuation or by displacement with air, steam or other gas or vapor.

Thus adsorbed water may be driven out by air at 115 deg. C., more rapidly at 125 deg. C., and still more rapidly at 150 deg. C. High boiling liquids may be adsorbed without difficulty, but require a correspondingly high temperature for recovery from the gel. Silica gel is almost ideally adapted to the adsorption and recovery of the vapors of liquids boiling between 30 and 150 deg. C. in that it takes up large quantities of these vapors at room temperature and gives them up readily at slightly elevated temperatures—that is, from 100 to 200 deg. C. This classification includes most of the important solvents, such as ether, acetone, methyl and ethyl alcohol, benzene, gasoline, methyl and ethyl acetates, and many others.

We shall see also that it offers a satisfactory means for drying air and for the recovery and concentration of the vapors of more volatile liquids such as sulphur dioxide.

A more detailed discussion of the theory of adsorp-

tion as applied to sulphur dioxide may be found in an article by John McGavack, Jr., and W. A. Patrick, in the *Journal of the American Chemical Society*, vol. 42, p. 946 (May, 1920).

LABORATORY RESULTS

Experimental results obtained on the laboratory scale, on the adsorption and recovery of sulphur dioxide, boiling point at -8°C .; ether, $+35^{\circ}\text{C}$.; acetone, $+56^{\circ}\text{C}$.; benzene, $+80^{\circ}\text{C}$.; water, $+100^{\circ}\text{C}$. and gasoline will be discussed in the order named.

SULPHUR DIOXIDE

The adsorption of sulphur dioxide by silica gel has been thoroughly studied both by the static and dynamic methods.

The static method consists in placing a convenient amount of the gel in a small apparatus which is then exhausted to the highest vacuum obtainable. To insure complete removal of air the vessel is heated to 300°C . and this temperature maintained, with the pump in continuous operation, for six hours, or until no more air can be pumped off. The pump used is the Gaeda high vacuum mercury pump. The vessel containing gel is then placed in a thermostat and a known amount of sulphur dioxide introduced. After the system has come to equilibrium, which requires not over fifteen minutes, the pressure is observed and the quantity of sulphur dioxide adsorbed determined. Fig. 1 gives the results of four series of results obtained in this way at 0, 30, 40, and 100°C . respectively. Fig. 2 gives a recalculation of these results in which the ordinates express the adsorbed sulphur dioxide as per cent of gel weight instead of cubic centimeters per gram of gel.

The dynamic method consists in placing a convenient quantity of granular gel, usually 10 g., in a glass tube of 1 to 2 sq.cm. in section bent in the form of a U for convenience of immersion in the thermostat, and passing through the gel at a given temperature a definite mixture of sulphur dioxide and air. The air and sulphur dioxide are metered separately through carefully calibrated flowmeters similar to those used by the Chemical Warfare Service, passing first into a

FIG. 3. ADSORPTION IN PER CENT OF SATURATED GEL WEIGHT

mixing chamber and thence over the gel. Under these conditions the gel adsorbs the sulphur dioxide completely for a certain period. At the end of this period a trace of gas begins to come through, the percentage of sulphur dioxide in the exit gas increasing rapidly, becoming finally equal to that of the entering gas. This corresponds to the point of saturation for this

particular mixture and temperature. The results of a series of experiments in which the concentration of the sulphur dioxide-air mixture varied from 0.5 to 8 per cent by volume and the temperature varied from 10 to 40°C . are given in Fig. 3. A comparison of Figs. 2 and 3 shows substantial agreement between the results given by the two methods. In other words, the presence of gas has, for practical purposes, a negligible effect upon the adsorption of sulphur dioxide vapor by silica gel.

The details of one set of experiments (at 20°C .) are shown in Fig. 4, in which the results are shown as percentage efficiencies against time. The ordinates here express the sulphur dioxide adsorbed as percentage of the total being admitted to the gel. With regard to these experiments we desire to make the following comments.

The rate of flow of gas through the gel was 40 c.c. per minute per gram of gel, or 0.65 cu.ft. per minute per pound of gel. This means that the time of contact

FIG. 4. PERCENTAGE ADSORPTION EFFICIENCY

of gas with gel was approximately 0.8 second. Notwithstanding this short interval allowed for adsorption, in each run no detectable trace of sulphur dioxide passed the gel for a considerable period. In other words, we had 100 per cent adsorption for a certain period, depending upon the concentration, after which the efficiency curve falls off abruptly to zero adsorption. We denote the time at which the first trace of sulphur dioxide comes through as the "break point." An examination of the curves at 20°C . will show that for all concentrations the gel was not less than 57 per cent saturated at the break point.

As already stated the rate used in these experiments was 10 c.c. per minute per gram of gel, which allows about 0.8 second for contact. If necessary, higher rates may be employed.

Fig. 5 shows that for a 0.75 per cent vapor the slopes of the efficiency curves are very nearly the same for rates ranging from 25 to 75 c.c. per minute per gram of gel. A practical rate for adsorption in general is 50 c.c. per minute per gram of gel, which is approximately 0.8 cu.ft. per minute per pound of gel. This allows about 0.6 second for contact.

The gel granules used in all these experiments varied in size between 8 and 14 mesh. The size of the gel particles has a very practical bearing in two respects. In the first place, it is obvious that the larger the particles the greater the time necessary for the adsorbed material to penetrate to the interior and that, for ad-

sorption purposes, it would be desirable to reduce the size of particles as much as practicable. The final saturation value would not be changed, but the break point would occur later and the latter part of the efficiency curve would be steeper, which is advantageous. Clearly, however, for the type of absorber being considered, there is a practical limit to the size of particles that may be employed, for it is obvious that the smaller the size the greater will be the pressure required to force the gases through the gel bed. Resistance to gas flow will be discussed further under "Experimental Plant Results" in Part III.

RECOVERY

With respect to the recovery of adsorbed material, silica gel has marked advantages over other adsorbents. By reference to the curves already given it will be seen that the gel takes up very little sulphur dioxide at 100 deg. C., even with high concentration. These curves indicate the obvious procedure to follow in using the gel. Adsorption should take place at as low a temperature as is practical, and for recovery the whole should be heated to 100 deg. C. or more. The exact procedure to be used depends upon the concentration of sulphur dioxide desired.

Let us assume, for example, that we have a gas which is 4 per cent sulphur dioxide by volume, and that we

FIG. 5. COMPARISON OF EFFICIENCIES

wish to concentrate this to 8 per cent for use in the lead chamber process for making sulphuric acid. And let us assume an adsorption temperature of 30 deg. C. We see from the curves that using a 4 per cent vapor and working at this temperature, the gel will take up 6 per cent of its own weight of sulphur dioxide. After adsorption the temperature is raised to 100 deg. C. and the sulphur dioxide swept out by means of an air stream, the volume of air being so regulated to give the desired concentration. We may, if it is so desired, obtain in this way a much higher concentration than 8 per cent. It is possible to go from 4 to 30 per cent in one step by simple air displacement at atmospheric pressure. It is easily possible in this way to concentrate as lean a gas as 1 per cent to 8 per cent in one step.

If the object is to obtain high percentage, as for example in making liquid sulphur dioxide, air would not be used, but the adsorbed SO_2 liberated at 100 deg. C. or above, by evacuation. By proper regulation of temperature, pressure and volume of air admitted any desired concentration up to practically 100 per cent may be obtained.

Parts II and III will be published in subsequent issues.

Diatomaceous Earth

BY NORRIS GOODWIN

THE last five or six years have witnessed a great awakening among the industrial minds of this country to the value of the so-called industrial minerals. Chief among these in variety of uses if not on actual volume of production is diatomaceous earth, or kieselguhr. The history of this material may be traced back to the sixth century A.D., when its use in the manufacture of lightweight fireproof brick and building material was certainly understood. Its use, however, passed into a long period of darkness, along with so many other useful arts known to the ancients, that have been brought back to the service of mankind in only comparatively recent times.

The immediate cause for the introduction of the material to modern trade seems to have been the rapid growth of the use of high-pressure steam for power and heat during the early part of the nineteenth century. The conveying of high-pressure steam to any distance from its point of origin made the use of some form of insulation essential, and the credit for adapting kieselguhr to this purpose appears to belong to the Germans, who about 1860 began to mine it near Luneberg, Hanover, and to market it as a steam pipe covering. So valuable a material could not be ignored in other lines, however, and its uses have gradually spread until today over one hundred and fifty separate and distinct uses for it could be enumerated.

ORIGIN OF DIATOMACEOUS EARTH

The material as it is quarried looks very much like chalk, and in fact it may supplant that material in the manufacture of blackboard crayons. Strictly speaking, it is composed of the siliceous skeletons of countless millions of diatomacea or infusoria of both fresh water and marine origin. So small are these skeletons that one cubic inch of the earth may contain fifty or seventy-five million skeletons. Microscopists have classified many thousand varieties of these dainty fossils; in fact they will remain one of the most fascinating fields of microscopic research.

Much interest attaches to large deposits of diatomaceous material, particularly in the West, by reason of its proximity to the known oil fields. In fact there seems little question that it is the primary source of the asphaltic petroleum of these regions. The theory is that by a process of decomposition under the influence of heat and pressure the bodies that originally inhabited these skeletons have been converted into the hydrocarbons comprising petroleum. So porous are the beds left behind that they would offer but little resistance to the displacement, by water or gravity, of the oil to the nearby strata. Strength is given to these conclusions by the presence in German kieselguhr of as high as 40 per cent of organic matter much resembling petroleum.

From a commercial standpoint the value of the material depends on the nature of its silica content and on the shape of the individual skeletons.

Just what condition the silica, that makes up from 75 to 95 per cent of the earth, is in, is not as well known as might be desired. Possibly it is a colloidal hydrated silica with proportions of the opaline variety which vary with the source, age and previous treatment of the earth in question. The main impurity, which

may run from 0 to 15 per cent, is clay, besides which lime, magnesia, iron oxides and organic matter may occur in minor proportions.

Geographically it is distributed in nearly every country of the world, but probably the largest single deposit of pure material is that at Lompoc, Santa Barbara County, Cal., where there are at present several companies engaged in actual production. Here the material occurs in thick beds, varying in color from pale brown to pure white and in texture from a soft clay-like mass to a hard flint-like diatomaceous shale. Gem opals are found at times in the bed of the mass. The mining is simple, open quarry methods being used. After quarrying, the material is allowed to stand in the air for some time to dry, after which it is pulverized and settled out of a current of air which grades it according to size.

USES OF DIATOMACEOUS EARTH

Without question, the two largest uses at the present time are for heat insulation and for filtration, both of which depend more on the physical than the chemical composition of the material. As a thermal insulator it is without peer, for, besides its ability to withstand a high heat and a corrosive atmosphere, its billions of inclosed air cells offer an almost perfect barrier to the passage of heat. Bonded with lime it is marketed in the form of brick and tile, while in the powder form it is packed loose in specially constructed furnace walls, or is mixed with small quantities of bonding materials for direct application as a plaster. At times small quantities of effervescing materials have been added with the bonding agent to increase its porosity.

As a filtrant it is used directly as a filter body and as an added filtering agent to maintain the filter cake in a porous condition. It also has some considerable decolorizing powers and has been applied either alone or mixed with fuller's earth to the filtering of vegetable and mineral oils, sugar solutions, and in fact wherever a mild decolorizing agent combined with an efficient filtering body is desired. To what particular property of the earth this decolorizing action is due is a disputed question. In the light of recent researches into the properties of silica gels, it might be thought that the answer was close at hand, yet many authorities with years of practical experience behind them stoutly maintain that the only criterion is the nature of the individual diatoms as shown by a careful microscopic examination. At least it appears that the small honeycomb-shaped diatoms have a greater decolorizing power than the long rod-shaped varieties, yet this may also be explained on the basis of the surface exposed.

The same qualities which go to make diatomaceous earth invaluable as a heat insulator and filtering agent also make it of value in many other ways. Mixed with lime or gypsum it has found use both as a building plaster and a fertilizer. L. Kern has found that when it is saturated with waste sulphite liquors it makes a good fertilizer (U. S. Pats. 1,144,905, 1,145,370). Peterson-Hviid has found it suited to the manufacture of casein glue in that when added to the freshly precipitated curd it renders uniform the drying and oxidation and makes the resulting products more easily soluble in alkali (British Pat. 1,016 of 1914 and Danish Pat. 18,160 of 1913). As a basis for plastic compositions its use is obvious. In the hydrogenation of vegetable oils some rigid yet porous support for the catalyzer is often a great advantage, and here again diatomaceous earth is more suited than any (U. S. Pat. 1,167,915). German

Patent 291,792 of 1913 refers to the use of vanadic acid precipitated on kieselguhr in the manufacture of sulphuric acid by the contact process.

Since a considerable portion of the silica in diatomaceous earth is soluble in alkali it has been used to some extent in the manufacture of sodium silicate in place of the more difficultly soluble quartz. Only the purest grades free from iron are adapted to this purpose, however. The same fact is responsible for its use in the manufacture of ultramarine.

Many of the early dynamites were compounded with kieselguhr as an inert absorbent, and a list of the commercial products depending on it as a filler would include rubber, phonograph records, sealing wax, match heads, soaps—in fact any product where a light, cheap, inert filling agent is desired. Even the sacred realms of death itself have been invaded, for we have the word of O. Gangloff (D. R. P. 291,526 of 1914) that mixed with naphthalene and paraffine it makes a most serviceable covering for coffins.

The bibliography given herewith, although not as exhaustive as could be desired, mentions most of the important articles which have dealt with this interesting material in the last few decades.

BIBLIOGRAPHY OF DIATOMACEOUS EARTH

Also known as kieselguhr, infusorial earth, celite, moler, bergmehl, English rotten stone, tripoli, fossil earth, desmid earth, white peat, tellurine, randanite, ceysstite.

Defects in Steel Originating in the Ingot

Microscopic Appearance of Breaks and Inclusions of Non-Metals in Steel, Which Defects Originate During Pouring or Solidification—Various Deoxidizers and Their End Products Are Listed and Briefly Discussed

By AUSTIN B. WILSON

DEFFECTS may be defined as those substances and conditions in the metal which make for failure during normal fabrication or in service. Different classifications might be proposed in a systematic study, but in the present article the writer intends to deal with those defects in steel, as they appear under microscopic examination, which originate in the pouring and solidification of a steel ingot.

OVERHEATING MOLTEN STEEL

Under this heading those defects caused by overheating the molten metal would naturally come first. Aside from the danger of change in chemical composition due to loss through volatilization, oxidation or undesired reaction with the furnace lining or slag to which overheating may give rise, the ever-present danger of the finished steel containing oxidation products is greatly augmented. Under favorable conditions it will lead to the presence of oxides of silicon, manganese or iron in the finished steel, possibly in such amounts as to affect seriously the physical properties of the steel.

Absorption of gases is another of the ill effects which are promoted by the overheating of the molten metal. Of the gases absorbed during overheating, oxygen, hydrogen and nitrogen are by far the most important and the most commonly encountered. These gases may be present in the finished steel in any or all of the following forms: Mechanically entrapped either in blowholes or between the crystal boundaries; in solid solution in the steel; or as compounds such as oxides, nitrides, etc., either in suspension or in solution in the steel. It is noteworthy that these gases are more

soluble the higher the temperature and that this solubility increases rapidly once the melting point is passed. Therefore the danger from overheating must be obvious. Hydrogen is known to cause brittleness and hardness in electrolytic iron, and nitrogen in the form of iron-nitride is the source of extreme brittleness in welds made by fusion with the oxyacetylene blowpipe or with the electric arc.

No new constituent is directly traceable to the absorption of hydrogen. Nitrogen, however, is commonly found in the form of iron-nitride in acetylene and arc welds and in blown bessemer steel before the recarburizer has been added. Fig. 1 is of iron-nitride in a piece of nitrogenized iron wire. It shows isolated needles of iron-nitride and several areas of iron-iron nitride eutectoid.

The quantities of gases absorbed are exceedingly small when measured by weight, but when measured by volume in many cases they greatly exceed that of the steel—silver, for instance, having been known to absorb up to 200 times its volume of gases. Furthermore, when in their combined forms they furnish a very appreciable amount of impurity—for instance, 0.046 per cent oxygen in steel is equivalent to 0.2 per cent FeO, which is readily noticeable.

WILD HEATS

On casting overheated steel which has absorbed an excessive amount of gases a sudden evolution of gas is not unlikely, sometimes of such degree as to cause the metal to boil over in the molds. This may be due to evolution of hydrogen, nitrogen, etc., caused by the lowering of the solvent power of the metal for gases due to reduction of temperature or to the formation and giving off of CO or CO₂ formed through chemical reaction in the mold. Whatever the cause may be, the net result is blowholes and the production of unsound steel.

Wild heats are rare in good practice. Blowholes are almost always present in ingots, but may be so controlled that sound finished steel may be produced. "Killing" the steel in the furnace with ferrosilicon or by the addition of a little aluminum in the mold greatly reduces the liability to blowholes. This is not, however, good practice, as it is difficult to rid the steel of the oxidation products. It is thought that this reduction of blowholes is due to an increase in the solubility of the metal for gases caused by the silicon or aluminum additions. Blowholes which have become oxidized are not capable of being welded, but those with bright, unoxidized linings weld readily during forging or rolling.

An exceedingly high casting temperature should be avoided. This leads to unduly slow cooling, which in

FIG. 1. EUTECTOID OF IRON AND IRON-NITRIDE, NEEDLES OF IRON-NITRIDE. X 400. ETCHED WITH HNO₃

turn results in a very coarse structure and excessive segregation. In castings it is quite liable to cause cracks due to shrinkage, and even if cracks do not result at once severe internal strains may be set up which will exert an unfavorable influence upon the serviceability of the piece in question. Fig. 2 is a shrinkage crack found in a casting poured at too high a temperature.

Although in forged or rolled material the original coarse grains are usually broken up and refined and the segregation more or less removed by suitable heat treatment, this is frequently not the case with castings. These are as a rule submitted to a single annealing. This annealing may produce the desired result in so far as carbon distribution is concerned and yet may fall far short of producing a sufficiently well-annealed casting. Particularly is this the case in castings of nickel steel, in which, as is known, the nickel is present in solid solution with the iron. During and immediately after solidification all constituents of the steel are entirely in a state of solid solution; therefore it follows

FIG. 2. SHRINKAGE CRACK IN STEEL CASTING. $\times 200$

the laws governing freezing solid solutions—i.e., selective freezing takes place, producing the familiar cored dendritic structure with layers of varying composition. On cooling through the critical range pearlite is formed as usual, but so far as the metals which form solid solutions with iron when cold are concerned no change is produced. These metals are chromium, nickel, phosphorus, silicon, etc. Upon reheating above the critical

Fig. 3. Pearlite dark, ferrite light in nickel steel casting. Picric acid etching. $\times 300$.

Fig. 4. Dendrites shown by etching with cupric chloride, same steel as in Fig. 3. $\times 15$

point and allowing to cool either in air or the furnace we obtain a uniform structure of ferrite and pearlite, but still the original distribution of the nickel, phosphorus, etc., remains. To obtain the desired diffusion of this it is necessary to heat the metal to a high temperature for a long time, say 1,100 to 1,200 deg. for twenty-four hours, after which it is given the usual heat treatment to produce a fine pearlite structure. In Fig. 3 is shown the typical well-annealed pearlitic structure brought out with picric acid. Fig. 4 shows the coarse dendritic structure brought out with cupric chloride, the lighter areas being higher in nickel. Both are the same specimen of 3.5 nickel steel, and show the survival of a coarse dendritic structure even after proper distribution of the carbon has been attained.

NON-METALLIC INCLUSIONS

A prolific source of non-metallic inclusions in steel is in the admixture of foreign matter. This may be due in castings to loose grains of sand from the mold or from the abrading action of the stream of metal on the surface of the mold. In case of ingots for forging, rolling, etc., it may be due to insufficient cleaning of the molds.

An instance of this kind has recently come to the writer's attention. A slightly greenish substance (apparently some form of slag) was found in the center of a 4 x 4 in. soft steel billet. After polishing a microsection cut through this spot it was seen to have the appearance and structure shown in Fig. 5. The slag was composed of two constituents, one a light gray and the other a darker gray. The lighter gray spots were at first supposed to have been MnS , but a sulphur print showed little sulphur at that spot. It was de-

Fig. 6. Same type of inclusion as in Fig. 5, after etching with nitric acid, showing lighter constituents eaten away. $\times 70$.

Fig. 7. Grains of sand sintered together, found in steel casting. Unetched. $\times 150$.

Fig. 8. Typical silicate inclusions in steel casting. Unetched $\times 150$

Fig. 9. Typical silicate inclusions (darker) and MnS (lighter) in rolled steel. Unetched $\times 150$

cided that the darker constituent was some basic substance high in lime, as it was readily attacked by HNO_3 , which is contrary to the behavior of silicates. Fig. 6 shows how the darker constituent was eaten away after etching it. It will be noticed that the slag is considerably broken up and evidently had been solid, not fused, at the time the steel entered the mold. The steel shows throughout as white masses. It was thought that this inclusion might have come from the lime wash used drying on the molds and then flaking

especially castings. It is supposed to heighten the solubility of the gases in the metal and thus prevent blowholes. It has a high affinity for oxygen and oxidizes readily to silica (SiO_2), reducing most of the oxides in the steel to their metallic form. Steel "killed" with silicon sets quietly with little evolution of gases. It may be added in the furnace, in the ladle or in the mold, usually in the form of ferrosilicon. Silica is acid and combines with iron and manganese oxides to form silicate slags. These silicates are sometimes mechanically trapped in the steel, especially if the steel has been treated with an excess of ferrosilicon. They are extremely hard and brittle and form dangerous discontinuities in the metal. Figs. 8 and 9 are examples of silicates in steel. Fig. 8 shows an exceedingly dirty spot in a steel casting, the silicates being present in the globular form commonly found in castings. The ferrosilicon in this case was added in the ladle. Fig. 9 shows typical elongated silicates found in rolled and forged materials. The darker inclusions are silicates and the lighter manganese sulphide. This photograph was taken from a low-carbon plate which had been "killed" by the addition of ferrosilicon in the mold. As a rule little objection can be raised to the use of silicon as a deoxidizer if not used in excessive amounts, although the danger of segregation such as shown in Figs. 8 and 9 is ever present.

MANGANESE SULPHIDE

Manganese is a deoxidizing agent to the use of which no defects can be attributed. Rather can they be charged to the lack of this element. Enough man-

Fig. 12. MnS arranged around the grains in a steel casting. Unetched. $\times 150$

off when the steel entered. Subsequent investigation proved this theory correct.

Foreign materials also very frequently enter steel by the abrasion or fluxing of the stopper rods and ladle linings. Fig. 7 shows a number of grains of sand sintered together found in an acid open-hearth casting.

In dealing with the subject of defects in steel naturally the use and abuse of deoxidizing agents assume prime importance, since it is generally held that the larger number of non-metallic inclusions in steel, or "sonims" as they are now called, arise from this source. Silicon, manganese, aluminum and titanium are the principal deoxidizers used in the manufacture of steel.

Silicon is used extensively in producing sound steel,

manganese must be present to form MnS with all the sulphur, since if sufficient is not present the sulphur will combine with some of the iron to form FeS, which has an embrittling effect and which is the cause of "red-shortness" in the steel. Iron sulphide can be readily recognized under the microscope by its pale yellow color as distinct from the dove-gray color of MnS. Manganese to the extent of at least two and a half times the amount of the sulphur present is required to prevent the formation of FeS. Oftentimes, despite the fact that chemical analysis shows the presence of sufficient manganese, microscopic examination will reveal sections in which FeS predominates. This is due to sulphur segregating in one part of the steel to such

Fig. 13. Segregated alumina in web of failed rail, black area in corner is part of a crack. Unetched. $\times 100$

Fig. 15. Alumina streak shown as surface defect in Fig. 14. Unetched. $\times 100$

Fig. 16. Alumina streak found in piece of broken drill. Unetched. $\times 100$

an extent that sufficient manganese to satisfy it is not at hand in that particular spot. Fig. 10 is an illustration of such a case found in a skelp sample which analyzed 0.06 sulphur and 0.27 manganese. The sulphides shown in the photomicrograph are practically all in the form of FeS and were the cause of extreme "red-shortness."

Nevertheless the presence of all the sulphur as MnS does not entirely remove danger. Although there is little cause to fear sulphides in the form of MnS if uniformly distributed, their segregation is to be watched for. A group of MnS inclusions will cause a brittle spot in the steel which may well be the starting point of a crack. In Fig. 11 is shown a crack extending through a group of segregated MnS spots. This photograph was taken from a rail which failed in service and in which the above segregated spot was the only defect which could be found, the steel being clean and its microstructure good.

Fig. 12 shows streaks of MnS arranged around the grains of a steel casting. This arrangement of the sulphides has a weakening effect upon the material, but at the same time it is of a type frequently met with in well deoxidized castings. In most cases, however, this condition is not widespread enough to have very serious effect.

ALUMINUM AS A DEOXIDIZER

Probably the most detrimental as well as one of the most widely used deoxidizers is aluminum. The bad effects resulting from its use are so well known that many specifications, such as the A. R. A. specifications

FIG. 14. SURFACE DEFECT ON WRIST-PIN OF AIRPLANE MOTOR. NATURAL SIZE

for rails, positively forbid it. Nevertheless, in many steel works it is still common practice to add a small amount either in the ladle or in the mold, although many of these plants when questioned regarding it deny its use in their works.

Aluminum is supposed to act in much the same way as silicon in producing sound steel—i.e., it increases the solubility of the gases in the metal. Aluminum, however, has a very marked effect in increasing the viscosity of the slag through its oxidation to alumina (Al_2O_3), which is an exceedingly infusible substance, its melting point being around 2,000 deg. C. Thus it can easily be seen that it solidifies immediately upon its formation, the temperature of the steel being at least 300 deg. C. lower than this. Fine particles of alumina do not readily coalesce and therefore in spite of their low specific gravity have no tendency toward rising and on mixing with the other small slag particles retard their rise and cause the bath to become thick and pasty, thus favoring the production of dirty steel.

If no other reason were forthcoming the above ought to be sufficient to inhibit aluminum's use, but that is

FIG. 17. TYPICAL TITANIUM-NITRIDE INCLUSIONS IN STEEL. UNETCHED. $\times 200$

not all. Although aluminum apparently has some effect in preventing the segregation of the constituents normal to steel, the particles of alumina exhibit a strong tendency to collect in large groups or masses which greatly reduce the strength of the steel. This is especially the case in worked material where streaks of alumina are often found, the weakening effect of which amounts almost to that of a crack. Fig. 13 shows a crack extending through a segregation of alumina found in the web of a failed rail. Fig. 14 shows a type of surface defect found in several hundred piston wrist-pins intended for airplane motors. The surface was ground from several of these pins to a depth of about $\frac{1}{16}$ in. and, the streak still remaining, it was polished and examined. Fig. 15 shows the streak of alumina as found with the aid of the microscope. Fig. 16 shows another exceedingly bad streak found in a specimen of broken drill steel. It is possible that the use at times of a very small quantity of aluminum, say a few ounces per ton, may be permissible, but at the same time the fact remains that even this is questionable.

FERRO-CARBON-TITANIUM

Although some metallurgists disagree, titanium in the form of ferro-carbon-titanium has been shown by many tests to be superior to all others as the final cleanser in steel-making. It cannot altogether replace either silicon or manganese, but it can take their place whenever they are used purely for deoxidizing purposes.

Titanium when added in the proper amounts makes the slag more fluid and acts as a flux for the various silicates. It has a high affinity for nitrogen as well as for oxygen, a property possessed by no other deoxidizer except possibly vanadium. It prevents segregation and does not itself segregate; in fact, except in high-carbon steels no microscopic constituent is found due to the titanium addition, and even in high-carbon steels it has never been known to segregate. When found in steels it is in the form of titanium-nitride, or rather titanium-cyanonitride, as it may be slightly contaminated with carbon. Fig. 17 shows typical titanium-nitride inclusions in steel.

In support of the views expressed above the writer quotes the following list of the properties of the various deoxidizers tabulated by Prof. Bradley Stoughton in the *Railway Age Gazette* of Feb. 7, 1913. The elements are given in the order of their effectiveness.

Prevention of blowholes 1, aluminum; 2, titanium; 3, silicon; 4, vanadium; 5, manganese.

19. PIPE LINED WITH OXIDE, FOUND IN WEB OF AN "A" RAIL, UNETCHED. $\times 200$

Removal of oxides of iron and manganese: 1, titanium; 2, silicon (weakly). Hindering this removal: 1, aluminum; 2, manganese.

Removal of all oxides and slag enclosures: 1, titanium. Hindering removal of all these enclosures: 1, aluminum.

Removal of nitrogen: 1, titanium; 2, vanadium(?).

Breaking up and removal of iron-sulphides: 1, manganese; 2, titanium(?).

Causing a pipe: 1, aluminum; 2, silicon; 3, titanium; 4, vanadium; 5, manganese.

Hindering segregation: 1, aluminum; 2, titanium; 3, vanadium. Promotion of segregation: 1, manganese; 2, silicon (sometimes).

PIPING

During the solidification of ingots a certain amount of piping, segregation and formation of blowholes is almost sure to occur. It is not possible to prevent entirely all these conditions, but the difference in the degree to which they are overcome constitutes much of the difference between good and poor practice.

A "pipe" in an ingot is in reality a shrinkage cavity, caused by contraction in cooling. The metal at the bottom and sides is cooled first by the chilling effect of the mold, and as it contracts is fed by the fluid metal in the center and top, with the result that a cavity forms in the top portion of the ingot. If cooled equally on all sides the "pipe" will occur in the center of the top of the ingot. If the ingot is "capped"—i.e., has a cast-iron plate clamped over the top as soon as filled to cause immediate solidification of the top—the "pipe" may be some distance below the top of the ingot. That a "pipe" is a shrinkage cavity has been proved by laying an ingot on its side before final solidification has taken place. In this case the "pipe" was distributed on the upper side along the length of the ingot instead of being confined to the top part. Fig. 18 A is a photograph of an ingot which had been laid on its side before final solidification, as just described. Compare this with B, which shows the normal occurrence of a "pipe"—i.e., in the top central portion of the ingot. The use of aluminum, silicon or any deoxidizer which causes the metal to set quietly increases "pipe" and usually necessitates the scrapping of a proportionately larger amount of metal.

Theoretically it should be possible to cast steel without producing a "pipe." This would be done by casting the metal at such a low temperature that solidification would take place the instant the steel entered the mold, the shrinkage thus being taken care of as the mold filled. Practically such accurate temperature control is not possible. The metal must be at a high enough temperature when tapped from the furnace to

Fig. 18. A. Left—Ingot laid on side before final solidification. B. Right—Ingot cooled in normal position

Fig. 20. Sulphur print showing segregation in "A" rail rolled from top of an ingot

Fig. 21. Sulphur print showing absence of segregation in "B" rail rolled from bottom of same ingot as "A" rail in Fig. 20

permit of teeming, and a safe margin must be allowed for any reasonable delay.

Blowholes can be so regulated that they occur only in places and under conditions which allow of their being welded in the subsequent forging or rolling operations.

Many ideas have been advanced for the production of sound steel ingots. Most of the plans put forward have been based upon the compression of the still liquid steel. Hadfield has suggested keeping the top of the ingot fluid by means of a charcoal fire and a blast of air, thus furnishing a "head" of liquid metal. Sound steel has been produced by almost all the methods suggested, but various reasons, usually cost of equipment or operation, have militated against their adoption.

The most practical method yet devised is the use of "hot-tops." A hollow fireclay tile is fitted on the

top of each ingot mold and when the ingot is teemed this is also filled. As the tile does not have the same chilling effect as the sides of the mold the metal contained therein remains fluid and by gravity feeds the metal in the mold as it contracts. Thus the entire "pipe" is usually confined to the "hot-top" and is easily removed by proper cropping. Since "piping" occurs in all steel where metallic shrinkage is not balanced by gas evolution (blowholes) and must be removed by cropping, it will be easily understood that a defect called a "pipe" in the finished product is in reality due to insufficient cropping. Fig. 19 illustrates the remains of a "pipe" found in a sample of rail.

SEGREGATION

Primarily segregation is due to the phenomenon known as selective freezing. This merely means that due to the various impurities it contains all portions of a steel ingot do not solidify simultaneously. When the liquidus of the particular alloy is first passed that part of the metal which is relatively more infusible solidifies. The more fusible portions—i.e., the portions containing the impurities—naturally solidify last and therefore are found in that portion of the ingot which is the last to freeze, usually the top central portion. Carbon, sulphur and phosphorus as well as most of the non-metallic inclusions tend strongly toward segregation when opportunity offers. Some of this segregation can be removed by proper heat treatment, but there is no remedy other than "cropping" for any serious segregation of non-metallic inclusions. The evil effects of segregation are many and will be encountered throughout the entire process if not properly dealt with.

Figs. 20 and 21 are sulphur prints of 90-lb. rails rolled from near the top and bottom respectively of the same ingot. Fig. 20 shows the typical segregation found at the top of the ingot. Fig. 21 shows a good homogeneous metal.

Fig. 22 illustrates the poor distribution of pearlite in a low carbon sheet-bar due to segregation in the ingot. At this stage of the manufacture it is impossible to correct this structure entirely, although it may to some extent be modified by suitable heat-treatment.

Niagara Falls, N. Y.

World's Industrial Exhibition in London in 1922

Announcement is made of a world's industrial exhibition, to be held at the Crystal Palace, London, during the months of May to October, 1922, of the industries, products, arts, sciences and inventions of the leading manufacturing countries of the world. It will be on a co-operative basis, the capital being provided by the exhibitors and those otherwise connected with the exhibition (such as the guarantors of each nation who guarantee sufficient for the preliminary work connected with the exhibition of their nation), and the profits accruing from the various sources of revenue, such as contracts for advertising, catering, amusements, season tickets, gate receipts, etc., will be apportioned pro rata among the exhibitors in order to bring the cost of exhibiting to the lowest possible figure.

Each country will elect its own exhibition committee, which in turn will be represented on the general committee. The management will be under the control of a committee representing the exhibitors and guarantors generally.

Possibilities for Research and Development in the Field of Refractories*

A Review of the Main Economic and Technical Factors Which Are to Be Taken Into Account When Research Work Is to Be Pursued on Some Particular Phase of the Industry of Refractories

By HOMER F. STALEY†

THE increasing use of refractories in well-known ways and the numerous demands for various kinds of refractories to be used for new purposes have created a demand for research. Moreover, the high price commanded by all sorts of refractories in the past few years has held forth the possibility of large pecuniary rewards as the result of successful research in this field. For these reasons there has been conducted of late a large amount of research dealing with refractories, some of which has been well planned and conducted along logical lines of procedure, but part of which has been ill-advised and from the very nature of the case doomed to produce no results of industrial importance.

It may be well then to make a brief survey of the field of refractories and to point out some of the phases of manufacture of these materials in which there is room for research and development.

ECONOMIC PHASES OF THE SUBJECT

If results of an industrial research are to be of large financial importance they must deal with some refractory which is or can be used in quantities with a high money value. In the accompanying table are given the value of the various refractories used annually in this country. It will be noted that out of the total of approximately \$72,000,000 \$11,000,000 represents the value of the clay refractories. Second in rank comes silica brick, with a value of \$20,000,000. Third in rank are magnesite refractories, with a value of \$6,500,000, while the bauxite and chromite refractories have a small annual value of about \$650,000 each. Therefore from a monetary standpoint the big opportunities for research are in fields of clay, silica and magnesite refractories.

Of the clay refractories, firebrick represent an annual value of \$36,000,000; glass pots and other glass house refractories a value of \$3,000,000; chemical porcelain and chemical stoneware of a little less than \$2,000,000; zinc retorts of a little over \$1,000,000, while all other clay refractories, including stove linings, saggers, mantle rings, muffles and crucibles, pottery supplies and miscellaneous materials, have a combined value of only \$2,000,000. It is evident, therefore, that the opportunities for research in clay refractories which may result in the saving of many millions of dollars annually lie in the possibility of improving the quality of firebrick, in lessening the cost of manufacture of these, or in producing a new product which can be used more economically. Research in other clay refractories

or in finding substitutes for these may result in moderate pecuniary reward to the investigator, but the product will probably never have a large annual value. If improvements can be made in the method of manufacturing silica and magnesite refractories, or if more economic substitutes can be found for these, the results of such research may possibly have large financial importance.

It should be remembered that the cost of refractories to be used for a certain purpose cannot be stated in terms of cost for unit of service. For instance, in the steel industry the cost of refractories is measured as cost of refractories per unit of steel produced. The item "cost of refractories" includes cost of firebrick and mortar, cost of repairs, including the charge for tearing out old material and replacing it by new, and, when two materials are being compared, the cost of interruption to manufacture incidental to the necessity for more frequent repairs when using one material than

ANNUAL PRODUCTION OF REFRACTORY PRODUCTS IN THE UNITED STATES

Clay refractories	
Firebrick	\$36,000,000
Glass house refractories	3,000,000
Chemical porcelain and chemical stoneware	1,750,000
Zinc retorts	1,200,000
Stove lining	675,000
Saggers	600,000
Pottery, pipes, stiles and spurs	275,000
Mantle rings, electrical resistance units, etc.	250,000
Muffles, crucibles, and crucibles	150,000
Miscellaneous	100,000
	\$44,000,000
Silica brick	\$20,000,000
Magnesite refractories	6,500,000
Bauxite refractories	650,000
Chromite refractories	650,000
	\$21,800,000

* This amount is the estimate of the U. S. Geological Survey for the year 1919.
† Estimate of the writer. The other amounts are rounded figures taken from those given in Mineral Resources of the United States, 1918, Part II.

when using another. In the same way in the pottery industry the actual cost of saggers is only incidental to the loss of ware and production caused by the breakage and failure of saggers. It may thus happen that an industry would be willing to pay more money for a refractory to use for certain purposes than it is now paying, provided the cost per unit of service with the new refractory is less than that with the one now being used.

In conducting a research to determine the probable life or service to be obtained from a new refractory care must be taken to consider the actual conditions of service in the industry. For instance, it has been demonstrated by laboratory tests that certain rather expensive sagger mixtures are more resistant to repeated heating and cooling and have higher transverse

* Paper presented at Chemical Exposition, New York City, Sept. 24, 1920.

† Chief Refractories Section, Bureau of Standards, Washington, D. C.

strength at high temperatures than those now in use. When these mixtures were tried out in actual practice in factories it was found that the breakage due to rough handling in setting and drawing kilns was so great that the estimated life of these saggars was reduced to the point where it was not profitable to use them. In another instance the use of fused alumina brick seemed to promise to be very satisfactory for the use of roof of electric furnaces. These brick were very refractory and showed marked ability to withstand sudden changes of temperature. However, when they were used in the roof of an electric furnace it was found that they failed, due to the fluxing action of lime vapors in the furnace. There is no question that brick could be made from more expensive materials which would be more resistant than firebrick to the temperature conditions and the slags used in blast furnaces; but these brick would be subjected to abrasion the same as the cheap firebrick now being used, and for this reason probably would not prove economical in use. We may rather definitely assume, therefore, that under existing conditions in a well-established industry none of the refractories now in common use are liable to be replaced by new refractories with comparatively excessive first costs.

On account of the importance of the practical and economic phases of research in refractories makers and users of these materials should work in conjunction with scientific research men. A rather ideal body for the formulation of research programs is one similar to that of Committee C-8 of the American Society for Testing Materials, which is composed of an equal number of representatives of manufacturers of refractories, of users of refractory wares and of men from research laboratories.

IMPROVEMENT IN CLAY REFRACTORIES —PHASE-RULE INVESTIGATION

Fireclays are essentially silicates of alumina carrying varying amounts of free silica in the form of sand and small amounts of potash, soda, lime, magnesia, iron and titanium. The phase-rule diagrams showing the effect of most of these materials on aluminum silicate have been worked out sufficiently to enable us to say that little is to be learned in regard to the practical utilization of clays done for refractory purposes by further application of phase rule studies.

The most important information obtained from these studies has been that calcined kaolinite must be considered as one point on the sillimanite-silica diagram. The eutectic between sillimanite and silica consists of 84 per cent silica and 16 per cent sillimanite, corresponding to 90 per cent silica and 10 per cent alumina.² It follows that the amount of silica-alumina eutectic in a clay is found by multiplying the percentage of silica in the calcined clay by 1 $\frac{1}{2}$. We can thus calculate that even in pure kaolinite 60 per cent of the calcined clay will melt at the eutectic temperature. The work of Montgomery and Fulton³ and other investigators has shown that the eutectic between silica and sillimanite is the dominating one in clays and that the effect of other impurities is simply to lower the eutectic temperature and to increase the amount of eutectic without

materially altering the ratio of silica and alumina entering into the eutectic. We may thus say that whenever the temperature is reached at which the silica-sillimanite eutectic becomes active the clay refractory consists of at least 60 per cent of melted material carrying the remainder of the refractories as unmelted material. The clay mass as a whole then gradually softens and becomes useless in refractory construction. The temperature at which this occurs varies with the composition of the clay and the structure of the mass, and the type of construction in which the material is used. In general we may say that clay refractories are not suitable for continuous use under load at temperatures above 1,350 deg. C., nor for use in structures where they are not subjected to load at temperatures above 1,450 or 1,500 deg. C.

PERMANENCE OF VOLUME

All clay refractories shrink during firing and when used in comparatively high temperatures are liable to continue to shrink. This lack of permanence of volume in use is one of the most flagrant defects of different types of clay refractories. In most cases it cannot be overcome, as is commonly assumed, by firing the refractory to a temperature equal to or slightly above that at which it is to be used. This shrinkage in use can be minimized by proper firing temperature, by selection of clays, by selection and preparation of grog material, and by variation in methods of manufacture. There is room for considerable research in developing clay refractories that will be permanent in volume up to temperatures of 1,350 to 1,450 deg. C.

GLASS HOUSE REFRACTORIES

During the past few years active research work has been done by a number of laboratories and by various individuals in connection with the improvement in glass house refractories. The most profitable line of research has dealt with the selection of clays, the preparation and sizing of grog and methods of manufacture. It is hoped that this work will be continued.

ZINC RETORTS

In microscopic study of used zinc retorts it has been shown that when clay retorts have been used for some time they are converted into what is essentially a mass of zinc spinel crystals. The possibility of making retorts from zinc spinel should be investigated.

SAGGERS

As stated above, while the annual charge for saggars in the pottery industry does not amount to a large sum, yet the loss of ware and production due to breaking of saggars is an important item in the pottery industry. It has been demonstrated that considerable improvement can be made in the length of the life of saggars by proper selection of clay both for bond clays and for grog and by proper sizing of grog. The use of such materials as sillimanite and carborundum for saggars is worthy of further study.

CHEMICAL PORCELAIN

While some of the chemical porcelain that has been made in this country has been of excellent quality, some has not. As far as use of clay ware for this purpose is concerned it seems that research and development should deal in this field of true high fire porcelain with glazes maturing at high temperatures. Since the

³*Trans. Am. Ceram. Soc.*, vol. 19, p. 303 (1917).

amount of body material used in this type of ware is small compared to the value of the finished product the use of some of the more rare and expensive materials in place of, or in combination with, clay has interesting possibilities.

MANTLE RINGS, ELECTRICAL RESISTANCE UNITS AND SIMILAR SPECIALTIES

While these are commonly classed as clay refractories, the use of pure magnesia and other special refractories in these in combination with clay is quite common, and there seems to be an opportunity for development of the use of various refractory oxides in these fields.

KAOLIN REFRACTORIES

Up to the present time practically all the clay refractories manufactured in this country have been made from fireclays. The use of kaolin as a refractory has been tried in an experimental way, and it has been shown that it can be employed to make a very high-grade clay refractory. The use of this material should be investigated further.

SILLIMANITE REFRACTORIES

As stated above, calcined clay represents one point in the silica-sillimanite eutectic series. By adding alumina to clay it is possible to get a composition that corresponds essentially to the mineral sillimanite $\text{Al}_2\text{O}_3\text{SiO}_2$. The most simple way of making sillimanite is by adding an ore of alumina to clay so as to bring the silica-alumina ratio up to that of sillimanite and then to burn the mixture in a kiln at a temperature not less than cone 18. Sillimanite can be made also by fusing a mixture of clay and coke in a cupola furnace and volatilizing the excess silica. This method has been used by Lacesne¹ in France and Malinowsky² in this country. Since with many ores of alumina there is a shrinkage in the formation of sillimanite in the kiln process, when these are used sillimanite must be made in one firing and the resulting material must be ground and mixed with a binder for the formation of wares which are then subjected to firing. Raw sillimanite mixture is a suitable binder for sillimanite made in this way or by the furnace process. A few ores of alumina, notably certain varieties of the diaspore clays found in Missouri, have so low fire shrinkage that it is possible to use them in connection with clay of low fire shrinkage for the manufacture of sillimanite wares in a one-fire process.

These sillimanite refractories have very desirable properties. The melting point is above cone 34, they do not soften at temperatures much lower than the melting point. When properly made they have permanent volume at elevated temperatures and resist sudden changes in temperature well. Up to the present time practically the only commercial use that has been made of this refractory has been in the manufacture of pyrometer tubes from what is known as Marquardt porcelain. There is a possibility of these refractories being used successfully for making saggers and crucibles and other refractories to be used at temperatures above those at which clay refractories give satisfactory service. For use in electric-furnace construction they have the advantage over silica refractories in that they are

not subject to destruction through volume changes. They are superior to carborundum refractories in that they do not deteriorate when they are used either under oxidizing or reducing conditions at high temperatures.

SILICA REFRACTORIES

The manufacture of silica brick in bulk shapes for furnace construction is the only important use of silica as a refractory in this country. We do not class fused silica ware, commonly called quartz glass, as refractory material. The making of silica brick has long been conducted successfully in this country by empirical processes, and the theoretical foundation of these has been studied thoroughly in the last few years.³ These have shown that the fundamental necessity for firing silica at high temperatures is due to the necessity for converting quartz into cristobalite and tridymite so as to avoid the volume changes undergone by quartz in heating and cooling. The one inherent defect of silica brick is that the cristobalite, which comprises their bulk constituent, is subject to sudden expansion when heated above 230 to 270 deg. C. and contraction when cooled below that temperature range. Therefore silica brick are not suitable for structures which are to be cooled periodically to atmospheric temperatures, but are very satisfactory for structures which are to be held continuously at high temperatures.

It is not probable that any improvement of marked commercial importance will be made by researches in silica brick manufacture. New uses can probably be found for these brick in structures that are to be held continuously at high temperatures. A promising field for study of uses for silica brick is in the construction of car-tunnel kilns.

MAGNESITE REFRACTORIES

Magnesite refractories are used for construction of those parts of metallurgical furnaces which come in contact with basic slag. The properties and processes of manufacture of these brick are fairly well understood. Their use is limited largely by the fact that they do not stand sudden temperature changes well and also are liable to shrink when held at high temperatures for long periods of time. Both these objections can be overcome by use of electrically fused magnesite with temporary organic binders or a small amount of raw magnesite as binder. This has been tried out on a small scale and the wares produced have been quite permanent in volume when exposed to high temperatures for long periods of time. Above 1,800 deg. C. they deteriorate by volatilization. It is probable that the use of electrically fused magnesite as a refractory will be employed for a special high-priced construction for the linings of electric furnaces.

Another magnesite refractory that shows promise of development is that of magnesium spinel, $\text{MgO} \cdot \text{Al}_2\text{O}_3$. This spinel can be made by calcining at high temperatures a mixture of magnesite and alumina ore. The calcined product can be made into wares by using small amount of the raw mixture as binder. Wares made in this way do not soften or deform below 1,800 deg. C. and do not deteriorate due to the volatilization of magnesia in the same way as pure magnesia refractories. The making of such refractories has been tried on a laboratory scale, and their use for the making of

¹J. Am. Ceram. Soc., vol. 3, p. 40 (1920).

²J. Am. Ceram. Soc., vol. 3, p. 160 (1920).

³C. N. Fenner, *Am. Jour. Sci.* (4th ser.), vol. 36, p. 339. D. W. Ross, Tech. Paper, Bureau Standards, 116.

small quantities of special comparatively high-priced refractories such as crucibles and pyrometer tubes seems a possible development.

CARBORUNDUM REFRACTORIES

In the past few years the use of carborundum refractories has reached a certain amount of commercial importance. The first attempts were made to bind the carborundum with clay, but lately it has been found possible to manufacture carborundum articles simply with the use of a temporary binder such as linseed oil, gluten or pitch. When the wares thus formed are fired to a high temperature, the temporary binder is burned out and the grains of carborundum are bound into a hard mass by the formation of carborundum crystals. Wares made in this way do not melt at any temperature, but dissociate and oxidize into silica and carbon very rapidly at 2,200 deg. C. This dissociation and oxidation are noticeable under oxidizing conditions at 1,500 deg. C. and under reducing conditions at temperatures above 1,700 deg. C. This refractory has the advantage over silica and magnesia refractories in that it is inert to basic and acid slags and that it is very resistant to all temperature changes. It can be used continuously at higher temperatures than either silica or calcined magnesite refractories. The heat conductivity is very high, which is an advantage for some purposes and a disadvantage for others. It has been used with satisfaction for the roofs of electric furnaces, but in such cases it has been necessary to cover the roof with a heat-insulating layer of firebrick and arrange to avoid contact of electrodes with any part of the roof. This latter caution has been found necessary on account of the high conductivity for electricity of carborundum refractories at high temperatures. It is probable that other uses will be found for this material.

ALUMINA REFRACTORIES

At present about the only use of bauxite brick is for the lining of the hot zone of rotary cement kilns. The factor that militates against its general use is the tendency to shrink continuously when exposed to high temperatures.

The use of fused alumina has been experimented with in the last few years. Products made from this material have constant volume and a high melting point. One difficulty has been to find a satisfactory binder. Clays have been used but the wares softened and deformed at the melting point of the clay used as binder. The use of raw mixtures which will form alumina compounds, such as magnesia spinel, as binders for this sort of material has been tried with promising results. Fused alumina materials up to the present have been used for making special small high-priced refractory pieces such as parts for electric tube furnaces, crucibles for chemical work, etc. There seems to be a field for this material in such uses, but it is not probable that it will ever be used for heavy refractory wares.

ZIRCONIA REFRACTORIES

Zirconia refractories have attracted a large amount of attention in the past few years. Zirconia ore from South America containing about 75 per cent ZrO_2 , the chief impurity being silica, has been used for making crucibles, brick and other refractories. Clay was tried as a binder at first, but it reduced the melting point of the refractory very remarkably. At present

finely ground ore is being used successfully as a binder. These wares must be fired to quite a high temperature if they are to be permanent in volume when exposed continuously to heat. The use of zirconium silicate, which is found in commercial quantities in this country, also gives promise of development. Attempts have been made to use pure zirconium oxide as a refractory for special purposes. In order to secure materials that do not crack in firing and change in volume and use, it has been found necessary to calcine the zirconium oxide at a very high temperature. In fact, the simplest method seems to be to fuse the zirconia in an arc. Since zirconia has a very high melting point, its use to a limited extent for refractories to be used at exceedingly high temperatures seems to be worthy of investigation.

CARBIDES AND NITRIDES

Of course, for continuous use under certain conditions it is essential that a refractory element be in a chemical combination which is stable under those conditions. For instance, in electric-furnace work it has been found that many of the refractory elements such as magnesium, titanium and aluminum form carbides when in contact with carbon or carbon vapors and that other elements under certain conditions at high temperatures form nitrides. This has logically led to researches having for their object the use of carbides and nitrides for refractories under the conditions stated. The employment of none of these materials has reached the stage of commercial importance at present, but active research along these lines is being conducted and should be continued.

REFRACTORY COATINGS

The technical literature in the patent records for the past few years has been full of references to attempts to use comparatively high-priced refractory materials for coatings for cheaper refractory materials. Some of these have been technically rather foolish—for instance, the use of thin coatings of carborundum to protect other refractories from the effect of heat. The conductivity of carborundum refractories is so high that the thin coating offers practically no protection against heat. Other futile attempts have been made to put coatings on refractory material when the coefficient of expansion or the shrinkage in use of the two materials varies materially. Another instance is the use of coatings or paints to produce a glazed surface on refractory materials. All such glazes reduce the refractoriness of the material so coated. Quite often the glaze is produced by the use of sodium silicate, which of course is a very effective flux. Such coatings may improve density and mechanical strength of the surface and thus protect the refractory against abrasion, the cutting action of flames, or against penetration by slag, but they certainly do not make the ware more resistant to heat. Similar compositions have been used for mortars in the building of refractory structures. There is no doubt that in some respects there is room for improvement over the common practice of using a fireclay chosen simply for its refractory properties. As mortars in structures subjected to cutting action of flames or corrosive action of slags, a vitrifying mortar would be more satisfactory. In any structure a vitrifying or semi-vitrifying mortar gives a structure that is stronger from the standpoint of mechanical strength. However, the composition of the material used for vitrifying mortar should be studied with care. Some of those

that have been proposed have been found injurious. There is room for research in the question of mortars for refractory structures.

INSULATING MATERIALS

At present the use of refractory material is in many cases dependent upon the fact that part of the refractory is kept comparatively cool by radiation. An instance is the use of refractories in the roof of metallurgical furnaces and ceramic kilns. Of course this radiation involves loss of a large amount of money. On account of the increase in cost of fuel in the past few years, the use of insulating materials for refractory structures has received considerable attention. It has been found in a number of cases that when the structure was insulated against loss of heat and the refractory materials thus became heated to a high temperature, they immediately failed. It is probable that if the use of heat-insulating coatings for refractory materials becomes common, the whole status of the use of various refractories in such structures will be materially changed and a revolution in the manufacture and use of refractories will take place. It will probably be necessary to use more expensive refractories and to develop the more general use of those now used but little. In certain cases it has been found that when insulating materials were used, the interior of the furnace walls became so hot that the insulating material failed, not by fusion, but by shrinkage. In connection with the use of some of the very high-grade refractories, there is need for the development of an insulating material which will function satisfactorily at high temperatures. In fact, it may be said that the whole question of the construction of electric furnaces with the use of high-grade refractories waits on the development of such an insulating material.

SUMMARY

Several factors must be taken into account when considering the possibilities for research in a particular phase of refractory industry or the development of the use of a new material as a refractory. The technical questions are the ones that are liable to seem most important to the research man, but the economic phases of the subject are fully as important. A certain amount of prevision is essential in considering such problems. A change in economic conditions or in modification of the methods of use of refractories may alter entirely the whole question of the manufacture of refractories and the possibility of the economic development of new refractories.

Improvement of Shantung Silk

An international committee for the improvement of Shantung silk has been organized at Chefoo, according to advices from Commercial Attaché Julean Arnold. For this purpose the Chinese Government has sanctioned the use of part of the export tax on silk from Chefoo, so that a sum of 150,000 taels (\$200,000) will be available annually for development and improvement work. Five hundred thousand mulberry trees are being purchased to aid in the development of mulberry silk. It is the aim of the association to improve both mulberry and tussah silk, which is produced by oak-leaf-fed silkworms, and it is hoped that through improved methods of reeling and the Pasteur method of egg selection greater market possibilities in America may be opened.

The Canadian Starch and Glucose Industry

The starch and glucose industry in Canada embraced twelve establishments in 1918, and the same number in 1917. The value of the total assets of the industry increased from \$3,670,806 in 1917 to \$3,784,664 in 1918, or 3 per cent. Included in this total, reports Consul Johnson, of Kingston, Ont., is the value of lands, buildings, fixtures, machinery, tools, materials on hand, stocks in process, finished products, fuel and miscellaneous supplies, which decreased from \$3,218,216 in 1917 to \$3,112,311 in 1918.

This leaves the increase in the cash and trading accounts at \$219,763, or 48.5 per cent.

EMPLOYEES AND WAGES—MISCELLANEOUS EXPENSES

In 1917 there were seventy-six salaried employees in this industry, who received a total of \$92,312, of which \$48,865 was paid to managers. In 1918 there were seventy-one in this class, receiving in the aggregate \$98,695, managers receiving \$49,440. This gives a per capita payment to salaried employees of \$1,215 in 1917 and \$1,389 in 1918. The average number of wage earners employed increased from 615 in 1917 to 633 in 1918; the total payment in wages rose from \$428,723 in 1917, to \$541,550 in 1918, or a per capita rating of \$697 in 1917 and \$856 in the succeeding year.

Miscellaneous expenses other than fuel, power, labor and raw materials, chargeable against manufacturing operations, rose from \$268,938 in 1917 to \$339,763 in 1918.

RAW MATERIALS USED

Approximately \$5,000,000 worth of raw materials was consumed by the industry in 1918, the chief items being as shown in the following table:

Corn (139,974,408 lb.)	\$3,858,312
Potatoes (9,923,279 lb.)	106,064
Cornstarch (503,950 lb.)	32,495
Sugar and syrup for mixing (1,657,082 lb.)	113,399
Containers of all kinds	750,560
Chemicals	44,763
All other miscellaneous material	87,112
Total	\$4,992,705

Cornstarch was used in one factory to make dextrine exclusively, but in three other plants it was used for the manufacture of both glucose and dextrine, so that it is not possible to determine the amount of starch utilized in the manufacture of either of these products. The principal commodity in the item "chemicals" is hydrochloric acid, which is used principally for the manufacture of glucose by the hydrolysis of starch.

PRODUCTS OF THE INDUSTRY

The industry's output in 1918 was valued (at the factory) at \$7,620,864, starch of various kinds and glucose forming \$6,327,515 of this total, as the following table shows:

Products	Quantity	Value
Cornstarch, lb.	19,041,506	\$1,445,324
Laundry starch, lb.	4,820,377	391,456
Potato starch, lb.	2,055,472	177,353
Chinese starch, lb.	1,263,227	122,284
Glucose (including all syrups), lb.	64,803,113	4,191,098
Grape sugar, lb.	688,378	37,392
Corn oil, gal.	242,451	404,659
Stock feed, tons	14,510	796,949
Dextrine, lb.	655,070	54,949
Total		\$7,620,864

Effect of Fittings on Flow of Fluids Through Pipe Lines

DEAN E. FOSTER presented the accompanying pipe-fitting equivalent tables and steam flow chart at the annual meeting of the A.S.M.E., New York, Dec. 7-10. To illustrate, an example may be taken of a 6-in. steam line 1,000 ft. long, containing five gate valves, three angle valves, twenty standard tees and ten standard elbows. From the lower table for vapors, these fittings are found to be equivalent to 332.10 ft. of 6-in. pipe, as follows:

5 Gate valves @ 4 81...	24.05
3 Angle valves @ 17 35...	52.05
20 Standard tees @ 6.35...	127.00
10 Standard elbows @ 12.90...	129.00
Total allowance...	332.10
Actual pipe length...	1000.00
Equivalent total length	1332.10

The chart shows that with an initial pressure of 150 lb. and a total loss of 5 lb. pressure or 0.375 lb. per 100 ft. this line will transmit 225 lb. of steam per minute. If the effect of the valves and fittings had been ignored, the calculation would show a capacity of 260 lb. of steam per minute.

The upper table for liquid flow is used in conjunction with standard tables, Cox's flow of water through pipes, etc., in a similar manner. In both formulas,

L_e = feet of pipe equivalent to fitting.

d = diameter of pipe in inches.

r = factor of resistance.

GRAPHICAL SOLUTION OF BABCOCK'S FORMULA FOR FLOW OF STEAM IN PIPE LINES

Determination of Atmospheric Impurities—II

A Description of the Nature of Atmospheric Impurities With Special Reference to Salt Lake City, Utah. Conditions—Methods and Apparatus Used for Their Determination—Results Obtained—Physical Character of the Solid Atmospheric Impurities*

By OSBORN MONNETT

A SUMMARY of the results of atmospheric analyses of Salt Lake City, as described in Part I, showing concentration of solids, carbon dioxide and nitrous acid together with accompanying weather conditions is set down in Table I.

SOOT FALL STUDY

Twenty locations for the placing of soot fall jars were selected. During September, October and November earthenware butter crocks about 5 in. in diameter were used. The crocks were easily broken by rain water freezing in them and the glaze tended to chip off and contaminate the soot collected. Enameled ware pails 6.5 in. in diameter were then substituted. Care was taken to set the pails at a sufficient distance from stacks to avoid local contamination. At intervals of about one month clean pails were substituted for the exposed pails, which were taken back to the laboratory for weighing and analysis of the soot. Some trouble was experienced from the chipping of the enamel on the pails and it is believed that a copper vessel would be more suitable where freezing weather is experienced.

The soot was filtered from the water on a weighed ashless paper. After drying, the paper was weighed again and the gain in weight calculated to tons of deposit per square mile per annum.

The papers were then ignited and again weighed in order to determine the amount of combustible matter in the soot. The amount of soot collected was insufficient for further chemical analysis—e.g., determination of tar or composition of ash.

Table II shows the soot fall in Salt Lake City from Sept. 5, 1919, to April 20, 1920, calculated to tons per square mile per annum.

Interpretation of Results. The following general conclusions may be drawn:

1. Total solids and total combustible matter are low during the heating season—i.e., November to February.

2. The per cent of combustible matter in the deposit is, however, higher during the heating season, rising from 30 per cent to 40 per cent.

3. The amount of material deposited is highest in the center of the city and in the vicinity of the railroad yards, being about 200 tons in the residence district and probably 800 tons in the business district and railroad yards.

4. The per cent combustible matter is highest in the center of the city and in the vicinity of the railroad yards, being about 40 per cent, as against about 30 per cent for the residence district.

5. Average figures for the part of the city covered over the entire period are: Total solids, 349 tons per square mile per annum; combustible matter, 122 tons per square mile per annum; per cent combustible matter, 35. Average figures during the heating season are: Total solids, 250 tons per square mile per annum; combustible matter 95 tons per square mile per annum; per cent combustible matter, 39.

It is evident that a large part of the material caught in the soot fall jars is of non-fuel origin. The amount of solids in the jars seems to vary with the wind velocity, decreasing from November through February and then steadily rising until in April the amount is over three times as large as in December, January or February. Microscopic examination of the precipitates collected during September, October, March and April shows large quantities of soil and organic matter, while the solids collected during November, December and January are practically all of fuel origin. This is borne out by the figures for percentage of combustible matter in the solids. This averages about 30 during September, October, March and April and rises to 40 during December and January.

Analyses were made of the water in soot fall jars for the periods Dec. 18, 1919, to Jan. 24, 1920, and Jan. 24

to Feb. 21, 1920. These are set down in Table III. Snow samples collected Dec. 15, 1919, at several locations in the city were also analyzed. The results have been set down in Table IV.

PHYSICAL CHARACTER OF THE SOLID MATTER ENCOUNTERED IN SMOKE ABATEMENT STUDY AS SEEN UNDER THE MICROSCOPE

The solid material collected in soot fall jars, which were placed in various parts of the city, was examined microscopically in order to determine the physical condition of the individual particles. Since this material had been exposed to the elements during the period of deposition, the jars contained more or less water when collected which necessitated filtering and drying. During the filtering and consequent drying, the fine particles of soot and ash became so thoroughly imbedded in the mesh

tain clinker or fused material, coke, ash, soot, woody fiber, dust or siliceous material, organic matter and lint.

Clinker. The material designated as clinker comprises that portion of the solid matter which shows evidence of having been fused. It appears in varying amounts in all the soot fall jars and presents some interesting features when viewed under the microscope. There are three types of the fused material: (1) the

TABLE IV. IMPURITIES IN SNOW

Snow collected Dec. 15, 1919: from 1 sq. ft. area to a depth of about 1 in. This gave about 2.3 liters of snow, which melted to about 0.6 liter of water. Snow on ground seven days.

Jar No.	Location	Tons per Square Mile per Annum	HNO ₃	NH ₃	Cl ₂	H ₂ SO ₄
1	756 N. 8th West	88	0.69			
3	914 W. 2d South	267	0.69	1.18	0.52

hollow type, (2) the globular solid type, and (3) the irregular shaped, slaglike mass type.

1. The hollow particles are black in color and have a somewhat rounded irregular form or shell. Owing to the thin shell, they are quite easily broken, especially so since the shell is quite brittle. In the case of the larger particles these shells have one or more openings which, from their appearance, have been caused by the sudden release of gas from within while the slag or clinker was in a somewhat semi-molten or viscous condition.

2. The globular or glassy appearing particles range in color from that of a clear glass, through pearly white and various shades of brown to a slag black. They are of all sizes and all are apparently solid.

3. The small particles of irregular shaped clinker present no particular features of interest, although it may be stated that many of the black slag-like grains are attracted by the magnet, due to the presence of a small amount of iron.

Coke. The particles under this head are not true coke, although they resemble it in appearance. They are partly consumed particles of coal which have been carried up and out of the flues by the hot gases before the process of combustion has been completed. Shaking the grates and raking the furnace fires would tend to dislodge material of this nature together with quantities of ash.

of the filter paper that only the coarser granular matter was available for microscopic examination. This coarse material was examined by means of the binocular microscope, the finer material being disregarded for the time, separate samples composed entirely of soot and ash being collected separately. It may be stated in a general way that the solid material collected in the soot fall jars is more or less similar in regard to the physical characteristics of the component particles. Practically the same class of solids was found in the jars from the different localities, although there was a noticeable difference in the amounts of the several classes of constituent grains and their size. When examined under the microscope the contents of the jars were found to con-

Soot and Ash. As before stated, the wetting received during exposure to the weather made it a difficult matter to examine the soot and ash content of the soot fall jars. The presence of these two constituents was apparent, however, since the rains and snow had washed them into the pores of the coke and irregular shaped particles where they could be distinguished under the microscope.

Woody Fiber and Dust. Salt Lake City has no wood block paving and the woody material found in the soot jars consisted largely of the debris of various types of vegetable matter such as grass, straw and dried vegetation in general, together with partly burned splinters of wood and charcoal. Siliceous particles and other mineral grains were noted under the microscope, although they comprise but a relatively small portion of the solid matter found in the jars. The presence of this material in the jars can be attributed to the action of wind and air currents which have carried it upward into the atmosphere, whence it settled. The amount of this material in the air diminishes to practically nothing during the winter months, when the ground is covered with snow for the greater part of the time. The charred wood and charcoal are of stove and furnace origin and small quantities of these two constituents are present throughout the smoky season.

Organic Matter. The organic matter in the samples consisted chiefly of the remains of dead insects, some of which had undoubtedly met their end in the jars, while in other cases their bodies had been deposited there through the agency of wind and air currents. The presence of this type of material is mentioned only as a matter of interest and merely shows that the air we breathe is laden to some extent with solids of many varieties.

JAR CONTENTS FROM DIFFERENT LOCALITIES

For the purpose of comparison, the solid matter collected may be considered under three heads: (1) Railroad yards and warehouse district, (2) business district and (3) residence district. The quantitative comparison, by weight, of the samples collected in the different localities has already been discussed.

The particles from the railroad yards and warehouse districts are as a rule larger in size than from either of the other districts and apparently contain a greater amount of unconsumed fuel or coke-like material. It is also noticeable that the relative amount of wood fiber, in

the form of straw and grain husks, is greater than in the downtown and residence sections. While the bomb-like and slaggy clinker material occurs in the jars from all three localities, the particles from the railroad district are larger in size than in the residential section. The greater size of the individual grains, together with the predominance of partially consumed material in the downtown and warehouse districts, constitutes one of the most noticeable differences in the soot fall samples from the three districts. There is apparently less ash in the warehouse and railroad samples than in the samples from the downtown and residence portions of the city.

SOLID IMPURITIES SUSPENDED IN THE ATMOSPHERE

The solid particles described represent the material which is of such size and weight that it does not remain suspended in the atmosphere for any great length of time. It settles out within a comparatively short interval after emanation from stacks and chimneys. There is another type of solid which has not yet been

TABLE V. SOOT FALL IN SALT LAKE CITY COMPARED TO THAT IN OTHER CITIES

considered and which constitutes a considerable portion of the atmospheric pollution during the winter months. Soot or carbon particles in the air form a very annoying form of nuisance. They are present at practically all times when the atmosphere is smoke laden and exist in all sizes from the large flakes which are visible to the naked eye to particles which are only resolved under a high-power microscope. Many of these soot particles are of sufficient size and weight to settle in a comparatively short time after their introduction into the atmosphere. Others which are of microscopic size will remain suspended almost indefinitely, depending on size, humidity, air currents, etc. Samples of this finely divided soot were obtained by the use of the Hill Dust Counter, and when examined under the microscope show the presence of many particles of carbon or soot which range from 25 microns (1 micron = one one-thousandth of a millimeter) in size down to particles which are just barely visible at high magnifications.

It has been shown by investigators of mine dust that comparatively few particles of dust larger than 10 microns reach the lungs and the same condition probably obtains with regard to the soot particles. That a considerable amount of soot particles are taken into the lungs is evidenced by the examination of the lung tissue of deceased persons who had lived in a smoke-polluted atmosphere. Sections of lung tissue of such persons show clearly the presence of particles of carbon when examined under the microscope. The amount of the carbon particles in the lung tissue depends largely on the length of time which is spent in a smoke-laden atmosphere, but it is certainly a fact that long residence in a smoky city results in the deposit of an appreciable amount of carbon in the lungs.

COMPARISON OF ATMOSPHERIC POLLUTION OF SALT LAKE CITY WITH THAT OF OTHER CITIES

Data for other cities are somewhat scanty and are not always expressed in units which admit of comparison with data obtained in Salt Lake City. The Chicago Smoke Abatement Commission¹ made a very thorough review of the literature on the subject of atmospheric pollution. The data here given have been taken from the above report.

Soot Fall. Comparison with results obtained in other cities is not easy owing to the difficulty in accurately estimating the composition of material collected in the soot fall jars. Obviously sand, soil and organic matter should be considered separately from that part of the solids which is of fuel origin. Except by laborious microscopic methods it is difficult to distinguish between coal ash and other mineral matter or between carbon from coal and that from organic matter.

In the winter in Salt Lake, with low prevailing winds and the ground covered with snow, it is safe to assume that the majority of the soot fall is of fuel origin. It is evidently these winter-time figures rather than the abnormally high spring-time figures which should be used in comparison with other cities where in general the smoke nuisance is not confined to one season as in Salt Lake. Such a comparison is made in Table V.

The mean soot fall for Salt Lake is as low as for any of the cities in the table. The maximum soot fall is higher than any with the exception of Pittsburgh and Glasgow. In comparison with its coal consumption Salt Lake shows a higher soot fall than any of the cities in the table, even if the smaller area be taken into account.

Other Impurities. In Table VI a summary of all data comparable with those obtained in Salt Lake City has been set down.

The table shows the concentration of solid matter in milligrams per cubic meter to be higher in the winter than for any other city with the exception of Cleveland.

Carbon dioxide does not differ much from the amount found in other cities.

Sulphur dioxide in Salt Lake is lower than in the other cities.

Sulphur acids in rain water and snow are about equal in amount to that found in Leeds and London.

Chlorine is low in comparison.

Nitrous acid is lower than in Chicago.

The maximum ammonia concentration is higher than in Chicago. Figured in tons per square mile per annum, the ammonia is about one-seventh that of London.

SUMMARY

A study of the character and amount of atmospheric impurities in the air of Salt Lake City has been made. This has included: 1. Estimation of the solids and gases present, including sulphur dioxide or smelter gas. 2. A soot fall study in which the amount of material settling at different locations has been measured and analyzed by months.

The results of this study show:

1. The concentration of solids in the atmosphere varies from less than 0.1 mg. per cu.m. to 2.5 mg. per cu.m. The highest concentrations occur during the heating season and in the business district. In the heating season these solids are practically all of fuel origin.

2. The total soot fall during the heating season averages about 250 tons per square mile per annum; 95 tons or about 40 per cent of this material is combustible matter.

3. Sulphur dioxide determinations showed an average concentration of 0.15 part per million during December and January and 0.01 part per million during March. The gas present is due to combustion of coal in the city. It is a negligible factor in the smoke nuisance.

4. The smoke concentration and soot fall is as high as that observed in cities consuming five to ten times as much coal yearly.

5. The results obtained afford a basis to judge the improvement made in future years.

Notes on the German Chemical Industry

Our correspondent in Germany reports on conditions in that country as follows:

The German dye trust, consisting of eight of the largest German chemical works, like the Badische Anilin- und Soda-Fabrik, Farbenfabrik Bayer & Co., Farbwerke vom. Meister, Lucius & Brüning, have decided to extend the life of its agreement, which was to run to Dec. 31, 1965, for another thirty-five years—i.e., up to the end of this century. Provision is thus made for a continuation of the present conditions for eighty years ahead. The firms in this trust have further decided to form a company with a capital of 500,000,000 marks to exploit the nitrogen industry. This company will take over the two nitrogen works in Oppau and Merseburg belonging to the Badische Anilin- und Soda-Fabrik. It is reported that the works at Oppau are fairly well employed. Of the normal number of workmen 8,400—6,000 are fully employed, while the remaining 2,400 will get full employment in the near future.

During the war the distribution of the total soda and potash production of Germany has been regulated officially by one of the so-called war companies. This state of affairs has now been terminated and the distribution has been given over to the trade again. This new step does not include the export and import, which are still tied to official licences.

The export of soda and caustic soda is still embargoed.

The demand for sal ammoniac has slackened considerably. The prices, which are regulated by the government, remain unchanged.

The demand for tar products is very strong. The demand for pitch, which was lifeless for a time, has now revived. Orders for benzene are still coming in with great pressure and can only partly be executed. The demand for cumaron has slackened and prices are going down.

Legal Notes

BY WELLINGTON GUSTIN

Directors Held Liable for Paying Unwarranted Dividends

The United States District Court, Eastern District of Pennsylvania, has decreed the directors of the American Galvanizing Co. to be personally liable for the debts of the insolvent corporation. Suit was brought against them by the United States Smelting Co. with the Picher Lead Co., Canada Metal Co. and Adam Hope & Co. as interveners. The case was before the same court in 1917 on a motion to dismiss the bill. The motion was dismissed and now a decree is entered against the directors. (261 Fed., 547.)

The American Galvanizing Co. had been in existence about nineteen months and was yet to declare its first dividend, when the directors declared a 500 per cent dividend. Almost immediately afterward the company by the act of these same directors was declared to be insolvent. It appears the company had entered into a number of contracts which began to mature and ripen into debt obligations payable about the time or shortly after the dividend was declared. It had outstanding contracts for the purchase of spelter, the raw material which it used in its manufacturing processes. These contracts proved the undoing of the company, as the drop in the price of spelter entailed a destructive loss upon it.

The company had done prosperous business and was in a prosperous condition at the time of the declaration and payment of the dividend. Including the contributions to its capital it had net assets valued at \$71,134.99, and a surplus applicable to the payment of dividends of \$58,940.85. Its capital stock was \$10,000. It was contended by the directors that at the time the dividend was declared there was not only nothing to indicate the imminence of a loss, but, on the contrary, much to expect in the way of profit on its spelter contracts, because the spelter market was trending upward at the time. However, the court found that the market at the dividend date was so feverish and fluctuating and the general conditions such that there could not be said to be any stable market, and difficulty of securing supplies was so great that there was uncertainty as to future market conditions and an even greater uncertainty as to the manufacturing business.

On the date of the dividend the matured payable debts of the company did not exceed \$2,200, but at the time of bankruptcy, a few months afterward, the total was many thousands, existing in the form of obligations resting upon executory contracts in the form of purchases of spelter for future delivery.

The court said that if there be actual fraud in the declaring of the dividend, then the statute of Pennsylvania making directors liable for the debts of the corporation if they declare and pay a dividend when the corporation is insolvent, or the payment of which renders it insolvent, need not be resorted to. The statute extends to cases beyond those of actual fraud. The measure of responsibility visited upon directors can be more readily sensed than expressed in a formulated rule

of conduct. Because this is true, said the court, no honest director need be troubled with doubts whether he should favor or protest the declaration of a dividend. "No board of directors by the declaration of a dividend insures the solvency of the corporation. Such directors are held in the discharge of their duties only to the standard of the bona fide exercise of their best judgments."

There was no finding of fraud in the case, but only of facts upon which the law visits upon the directors a legal liability to pay the company's indebtedness.

The Ornstein Process of Chlorinating Water Upheld in Federal Court

A highly beneficial chemical process, as regards the public, is discussed in a patent suit of the Electro Bleaching Gas Co. against William G. Miller and another in the United States District Court at Kansas City, Mo. The Electro company is the assignee of George Ornstein, the inventor of process patent 1,142,361, for antisepticizing water. The invention "comprises a method wherein chlorine in determined amounts is uniformly distributed through and absorbed by a minor body of water flowing as a continuous current, and said minor body is then uniformly distributed through a major body of water, also flowing as a continuous current, all said operations being conducted without pause sufficient to allow disappearance of any substantial amount of said chlorine as free chlorine prior to exercising its antiseptic action."

DETAILS OF THE PATENTED PROCESS

It is said that the apparatus by which this process is made operative comprises an absorption tower, through which the minor flow of water passes downward to absorb an upwardly moving current of chlorine gas. The chlorine is supplied from a tank of compressed and liquefied chlorine gas, from which a pipe leads into the lower part of the tower. The tank is provided with a shut-off valve, and the supply pipe with a pressure-reducing valve and a regulating valve. Water is supplied to the tower from any suitable source, giving a substantially constant head through a pipe which leads into the top of the tower, and is provided with a shut-off valve and a regulating valve. The water-supply pipe is also provided with means for measuring the water flowing through it to the tower. For this purpose a suitable meter for indicating the quantity of water which has passed through may be used. The chlorinated water from the tower is discharged through a pipe to be united with the body of flowing water to be treated. The minor flow of water, after being chlorinated in the tower, is discharged directly into the water to be treated.

The absorption tower is formed of a vertically set shell of earthenware or other suitable material resistant to chlorine, filled, or substantially filled, with broken stone, coke or other suitable distributing material, adopted to film out the water and cause it to present an extended area of surface for contact with the ascending current of gas. The chlorine admitted to the minor flow of water is measured in determined proportion to the amount of water to be treated, but not necessarily with exactness in proportion to the minor flow. By this method a better and more effective solution is obtained, and better diffusion and distribution in the water to be treated, resulting in more complete and satisfactory sterilization of the water to be treated, less waste and

loss of chlorine, and less injury to the metallic part of the structure through the destructive action of the chlorine than can be accomplished by direct methods of introduction of the chlorine into the main body of the water to be treated; also excessive chlorination, with its attendant disagreeable features, is avoided.

The two main elements of the invention are the minor continuous flow of water and the regulation of the current of chlorine gas introduced therein in an amount predetermined according to the volume of water to be treated. The first of these employs as its vehicle the absorption tower with its appurtenances; the second element the pressure-reducing and regulating valves, with their attendant mechanism commonly called "regulator."

The defendants in the case manufacture the "Miller chlorine gas pressure regulator." It appears that the Miller regulator had been used by the city of Chicago and elsewhere to replace the corresponding part in the Electro company's apparatus. Contributory infringement of the process was predicated upon this use, charging the process of antisepticizing water which constitutes the invention by substitution of the vital element performed by the regulator.

DEFENSES TO THE SUIT

There were two defenses to the suit: (1) That the alleged improvements set forth in the said letters patent were not novel and patentable when produced by Ornstein, and the patent is accordingly invalid. (2) Even though the patent be upheld, respondents are protected by the right of use, enjoyment, repair and improvement in the purchasers of the apparatus.

NO ANTICIPATION, SAYS COURT

The first defense rested on an earlier patent by Darnell, No. 1,007,647, which was claimed to anticipate Ornstein's process and thereby rob the latter of novelty necessary to invention. The Darnell patent does deal with sterilization of water by treating with chlorine gas. But the court found that it deals with the direct communication of the chlorine to the body of water to be purified as distinguished from the indirect method by means of a minor flow, which is the distinctive achievement and advance accomplished by the Ornstein process. The court found further that the indirect method was both disclaimed and discredited in the Darnell patent, which says:

"The chlorinated lime or soda, or the chlorine gas, has usually been mixed with a certain quantity of water, and determined amounts of this chlorinated water have been introduced into the effluvia to be disinfected. This is not an efficient method of using chlorine, because in the process of fluid sterilization by chlorine the principal disinfecting agent is not the chlorine itself but the oxygen liberated from water by the action of chlorine on the water. . . . When, therefore, chlorinated lime, chlorinated soda or chlorine gas is admixed with a quantity of water and this water is afterward used to disinfect or purify large quantities of other water a great loss of efficiency is the result."

MERE REFERENCE TO INDIRECT CHLORINATION DISCLOSES NO PROCESS

The court said the mere reference to indirect chlorination, without description and coupled with the declaration that such a method is inefficient, discloses no process and cannot anticipate even by suggestion.

Darnell, in this very language, discloses that the vital principle of the Ornstein process remained unperceived. He says the chlorine gas had usually been mixed with a certain quantity of water and determined amounts of this chlorinated water had been introduced into the body to be disinfected. In the methods with which he had been familiar, if any, says the court, it would appear that chlorine gas was admixed with a quantity of water and this water was afterward used to disinfect or purify. It had never occurred to those who were studying this problem and who were endeavoring to get successful and satisfactory distribution and conservation of the disinfecting property of the chlorine that a predetermined amount of chlorine, in exact proportion to the body to be purified, might be introduced into that body through the instrumentality of an active minor flow to the volume of which the amount of chlorine used need bear no fixed ratio.

The idea of chlorine in determined amounts being uniformly distributed through a major body of water by means of a minor body flowing as a continuous current and carrying the chlorine in solution had not yet been conceived, it was said. This was the pregnant contribution of Ornstein to this art. One witness in the case, Prof. Jackson, stated in substance that "Ornstein discovered a principle that accomplished a result which all scientific students of the art had been vainly seeking for years and which converted previous uniform failure into pronounced success. Since this invention, the Ornstein method is rapidly displacing other methods of water purification and has given abundant evidence of its utility." Therefore the court concluded that the patent was not anticipated in any prior patent or scientific publication, and that same is valid and of great value to the public.

CHARGE OF CONTRIBUTORY INFRINGEMENT UPHOLD

Passing to the charge of contributory infringement, the court stated the rule to be that "where a person furnishes a machine, composition of matter or other article which is particularly adapted to be used in performing a patented process and which the person furnishing the same intends shall be thus used, that person is liable, as a contributory infringer, for any infringement, which afterward occurs in accordance with his intention."

The right of replacement, improvement, substitution or resupplying of an element of a patented apparatus depends entirely on whether the purpose is legitimate repair in the sense of restoration of worn-out or broken parts, said the court. And in this case, where the owners of a process patent for purifying water licensed its use by purchasers of the apparatus by which it was made operative, defendants, who sold a device to two of such purchasers, one of whom assisted in installing it in place of one of the parts of the patentee's apparatus, were held guilty of contributory infringement, where the substitution was not made because the part was worn out, and where the parts supplied were not small and trifling in character. Neither did the fact that the device was adapted to other uses, or was not identical in size or form with the corresponding element in complainant's machine, relieve from contributory infringement. Further it was said that where a patentee of a process licensed its use in connection with machines sold by him, the continued right to use it could not accompany any radical transformation of his machine by repairs.

Graphic Calculation of Neutralization of Caustic Liquors With CO₂

BY JOSEPH C. DITTMER

IN THE case for which the following method of calculations was originated, it was necessary to neutralize caustic soda liquor with carbon dioxide, the amount of liquor required for a given amount of gas being originally calculated by the foreman. As it was desired to have a simple method of calculation, and one which the average process-man could work, the following graphical method was devised.

There are three factors capable of variation: the amount of carbon dioxide, the amount of caustic liquor, and the NaOH contents of the liquor. The amount of sodium hydroxide in the liquor is difficult to control, so that to keep its quantity constant is very inconvenient, but the amount of carbon dioxide is easily regulated, as it is usually taken from weighed cylinders. The amount of carbon dioxide will temporarily be fixed at 250 lb., and the two other factors will be permitted to vary according to conditions.

CAUSTIC LIQUOR EQUIVALENT TO 250 LB. OF CO₂

The chemical proportions of caustic and carbon dioxide may be taken from the reaction:

from which the amount, x , of NaOH which 250 lb. of CO₂ will neutralize, is calculated as follows:

$$80:44 :: x:250 \text{ or}$$

$$x = (250)(80) \div 44 = 454.5 \text{ lb. of NaOH}$$

An analysis of caustic liquor gives 10.0 g. of NaOH in 100 c.c.; specific gravity 1.238.

The total amount of liquor needed to supply 454.5 lb. of NaOH is calculated from the proportion

$$10.0:123.8 :: 454.5:x$$

$$\text{or } x = (454.5 \times 123.8) \div 10 = 5,626.71$$

As the tank measures 5 ft. in diameter, the volume of 1 in. in depth is:

$$0.7854 (5^2) \div 12 = 1.63625 \text{ cu.ft.}$$

The weight of this volume of liquor is:

$$(1.63625)(1.238)(62.5) = 126.6 \text{ lb.}$$

The number of inches of liquor needed is:

$(454.5)(123.8) \div 10 = (102.26)(1.238) = 44.45 \text{ in.}$
of liquor from 5-ft. tank to neutralize 250 lb. of CO₂. Ten times 44.45 gives 444.5, which may be used as an equation constant for 250 lb. of CO₂, a 5-ft. diameter tank and a test sample of 100 c.c. at the temperature of the liquor in the tank. Dividing this constant by the grams of NaOH in 100 c.c. of the liquor, the inches of liquor required for 250 lb. of CO₂ is obtained.

For more or less than 250 lb. of CO₂—e.g., 150 lb.—the following relation holds:

$$44.45 (150) : 250 = 26.67 \text{ in. in 5-ft. tank.}$$

GRAPHICAL SOLUTION

To find the number of inches of liquor from a 5-ft. tank corresponding to grams of NaOH per 100 c.c. graphically, a curve from which these values can be obtained is developed as follows:

Using a base line equal to the diameter of a circle with a radius equal to $\frac{1}{2} \sqrt{44.45}$, or 3.333 u., a perpendicular line is erected at each end, the vertical line at the left being used for plotting grams of NaOH (1 g. = $\frac{1}{2}$ u.), and the line at the right inches of liquor (10 in. of liquor = $\frac{1}{2}$ u.). Connecting each value in grams of NaOH with the resulting value in inches of liquor by a line, a half circle is determined to which these lines are tangent.

If x grams of NaOH in 100 c.c. of liquor and y = number of inches of liquor for 250 lb. of CO₂, then $44.45 = xy$, as has been shown above.

For a value of x giving a line tangent to the curve and parallel to the base line: x must equal y . As the values of y , as plotted, are ten times those of x , $y = 10x$. Substituting this value in the equation $44.45 = xy$, gives $x = 6.667$. As $y = 10x$, $y = 66.67$.

As the values of x are plotted according to the scale 1 g. = $\frac{1}{2}$ u., a half circle drawn with a diameter of 6.667 u. will give the curve to which lines connecting "grams of NaOH" and their corresponding number of inches of liquor are tangent.

The diameter of the circle, 6.667 u., is based on calculations using 250 lb. of CO₂ and is shown in the accompanying figure.

To determine graphically how many inches of liquor are required for more or less than 250 lb. of CO₂, connect the value of inches of liquor—e.g., point B on the accompanying diagram—with the origin (point C) by a line forming a right angle triangle. Erecting a perpendicular at the point of the amount of CO₂ to be used (e.g., 152 lb.) and extending it to meet the line BC at D, the length of this line DE or EG will give the amount of liquor required for the amount of gas taken (152 lb.).

This method of calculation can also be used when the amount of caustic liquor is constant and the amount of CO₂ is variable. For example, with liquor testing 10.0 g. NaOH per 100 c.c. and given 26.7 in. of liquor, draw the tangent AB and the line BC. From the value 26.7 in. of liquor extend a line to meet the line BC and where it intersects at D, drop a vertical line, DE. The value at E gives the amount of CO₂ needed to neutralize this amount of liquor.

Using chlorine as the neutralizing agent, 250 (70.96) = 44 lb., or approximately 403 lb., would be required to do the equivalent amount of work. Putting the base line equal to 403 lb., it is a simple matter to calculate the amount of liquor required for a greater or lesser amount of this gas.

Static Notched-Bar Testing Machine

A NUMBER of notched-bar testing machines using the impact method for determining the quantitative measurement of the brittleness and ductility of steel and other metals have been designed. These differ largely in the method of applying the impact blow, of supporting the specimen, size of test-piece, shape and size of notch. The following is a description of the machine recently devised by J. C. W. Humphry.

In breaking a notched-bar test-piece there are two governing factors at each moment: the angle to which the specimen is bent and the resistance which it offers to the external bending force. If a notched-bar specimen is broken slowly by static pressure the work expended is comparable with that measured by a dynamic impact machine and is much more effective in distinguishing between brittle and ductile metals.

The test-piece *A* (Fig. 2) is gripped in the vise *B* so that the jaws of the vise are in line with the notch in the test-piece. The socket *C* is attached on the projecting end of the test-piece and is a reasonably close fit. A bending stress is applied to the test-piece by means of the winch *D* and the wire *E*. The inner end

FIG. 1. STATIC NOTCHED-BAR TESTING MACHINE

of the spring bar is firmly fixed to the socket *C*. The outer end of the spring bar is supported by two rollers *G* and *G*. The socket *C* also carries a rigid bar *H*.

The deflection of the spring bar *F* is a measure of the bending moment applied to the test-piece. Since the rigid bar *H* is not subjected to any bending moment it will move through the same angle as the socket *C*, and this movement will therefore be a measure of the bending of the test-piece. The pen *J* slides upon the rigid bar *H*, its position being determined by the thin wires or cords *K* and *L* which are kept taut by a light spring *M*. One end of the wire *K* is attached to a post *N*

FIG. ELEVATION AND PLAN

so that as the rigid bar *H* moves in consequence of the bending of the test-piece the wire *K* will draw the pen to the right. The point of the pen marks upon a calibrated chart *P* carried on the spring bar *F*; therefore if the test-piece offers no resistance whatever to bending force the pen would draw on the chart a

Fig. 3. A—Curve showing brittleness of nickel-chrome steel which has been made brittle by cooling from the tempering temperature. B—Curve showing ductility of a specimen of soft brass.

horizontal line, the length of which is proportional to the angle through which the test-piece is bent. However, as the test-piece does offer resistance to bending there will be resulting motion between the spring bar *F* and the rigid bar *H*.

Assuming the test-piece was infinitely rigid and did not bend at all under applied force, the pen would draw a vertical line on the chart, the height of this line representing the bending moment applied.

In actual practice, however, both of these effects are operative at the same time, with the result that with a brittle test-piece we get a curve represented in Fig. 3 by *A*, and with a ductile sample a curve shown by *B*.

The total energy absorbed in the breaking of the test-piece can, of course, be calculated easily from the diagram or graph. The machine is also fitted with an integrating device. This device is shown in Figs. 1 and 2. The wire *K* passes round a pulley *Q*. The pulley *Q* is attached to a spindle having at its lower end a friction disk *R* so that the bending of the test-piece, which results in the movement of the pen to the right, also results in a proportionate rotation of the friction disk *R*.

The lower face of the friction disk *R* rests upon the edge of the friction wheel, not shown. The spindle of the friction wheel is carried with the chart plate upon the spring bar *F*. When the bending moment is zero the friction wheel is at the center of the friction disk, but as bending moment is applied and there is therefore relative motion between the spring bar *F* and the rigid bar *H* the friction wheel travels toward the circumference of the friction disk and is consequently rotated. The rotation will be proportional to the product of the bending moment applied and the angle of bending of the test-piece, and this device will therefore integrate the total energy absorbed in breaking the test-piece. Mounted upon the outer end of the spindle which carries the friction wheel is an index disk *T*, which can be calibrated to read direct in foot-pounds.

The whole machine is mounted upon a rigid and heavy metal base *T* and is arranged for convenient and rapid operation by relatively unskilled users.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Vulcanizing India Rubber.—India rubber in solution is vulcanized by the addition of sulphur and small quantities of nitrosobenzene or a similarly constituted nitroso-hydro-carbon of the cyclic series. In an example, 10 g. of rubber and 1 g. of sulphur are dissolved in 150 g. of carbon disulphide. There is added 0.6 g. of nitrosobenzene and the solution shaken. In about thirty minutes the solution sets to a jelly which on evaporation of the solvent yields vulcanized rubber, insoluble in the solvents for raw rubber. (Br. Pat. 146,734—1919; S. J. PEACHLEY, Davenport, Stockport, Sept. 22, 1920.)

Separating Dust From Gases.—A device for removal of dust from gases evolved in the roasting of ores consists of a chamber in which the current of gas passes at right angles through curtains consisting each of several parallel rows of chains which may be magnetized, the curtains being separated by spaces forming depositing chambers; the chains of consecutive rows of a curtain being disposed so as to split the current up as much as possible. The chains of a row may be fastened together, while the chains of the rows forming a curtain are connected to wires by which they may be shaken at intervals when no gas is passing. Dust falling to the bottom is carried outside the chamber by a screw conveyor. The chains of successive rows of a curtain may be disposed in echelon vertically or horizontally. (Br. Pat. 147,020—1919; MANUFACTURES DE PRODUITS CHIMIQUES DU NORD, Etablissements Kuhlmann, Paris, Sept. 22, 1920.)

Phenol Aldehyde Condensation Products.—In the production of insoluble infusible condensation products from phenols and formaldehyde or its polymers, the phenol is first condensed with the formaldehyde in the presence of an ammoniacal catalyst (ammonium carbonate or phenate) and the product is heated at 75 to 80 deg. C. until its viscosity has considerably increased; it is then mixed with an acid catalyst, particularly ethyl hydrogen sulphate, and converted into the final product at ordinary or only slightly raised temperature. The ethyl hydrogen sulphate may be added in alcohol solution and the product employed as a varnish. The product of the first stage of the process may be acetylated by treatment with acetic anhydride, and the acetylated product then treated with ethyl hydrogen sulphate. The acetylated products may be mixed with acetone solutions of cellulose acetate. (Br. Pat. 147,173—1919; J. FRIOL, Lyons, France, Sept. 29, 1920.)

Treating Cellulose-Containing Materials.—To avoid the deleterious effect of alkalis, acids and salts on cellulose fibers and also on the byproducts resin, tannin, carbohydrates, etc., due to the high temperatures obtained in the ordinary methods of treating wood and other cellulose-containing materials under pressure,

the pressure is produced externally and independently of the temperature used, by forcing or pumping air or other gas or suitable liquids, such as that used for treating wood, into the apparatus in which the material is being treated. Fifty atmospheres pressure or more may be used. The apparatus may be first exhausted, and alternate vacuum and pressure may be applied repeatedly. The process may be applied to reagents used for other purposes such as saccharification. (Br. Pat. 147,232—1919; ZELLSTOFFFABRIK WALDHOF, Mannheim, Germany, Sept. 29, 1920.)

Precipitating Bath for Artificial Threads.—A precipitating bath for artificial threads, etc., more particularly of viscose, consists of the crude mixture of carbohydrates, etc., obtained on hydrolyzing wood or other cellulose-containing materials with mineral acid; the acid in the bath may be partly or completely neutralized, and other reagents such as ammonium sulphate, sodium bisulphate, formic acid, lactic acid and alum, may be added. In an example, sawdust is kneaded with 80 per cent sulphuric acid, left to stand, diluted with water, and the mixture heated; the hydrolyzed mass is concentrated, partly neutralized, filtered and treated as above, or it may be completely neutralized and concentrated to a sirup or to crystallization. (Br. Pat. 147,416—1919; ZELLSTOFFFABRIK WALDHOF and V. HOTTENROTH, Mannheim, Germany, Oct. 6, 1920.)

Hydrogenating Naphthalene.—Naphthalene is hydrogenated by treating while in the fused state and at a temperature above 100 deg. C. with hydrogen in the theoretical quantity and in the presence of a catalyst. Decahydronaphthalene or other less highly hydrogenated products are obtained, and these products are suitable as lamp, motor and lubricating oils, etc. In an example, naphthalene is purified by fusion with fuller's earth or other porous material, after separation mixed with a catalyst consisting of finely divided nickel precipitated on a porous material, and the spongy mass so obtained treated at a temperature of 120 to 150 deg. C. with hydrogen under 3 to 100 atmospheres pressure. (Br. Pat. 147,474—1919; G. SCHROETER, Berlin. See also Br. Pats. 147,476, 147,488 and 147,580—1919. Oct. 6, 1920.)

Alkali Hypochlorites.—A stable preparation for bleaching and disinfecting is prepared from alkali bicarbonates and solid basic magnesium hydrochlorite. In the form of tablets, the mixture remains undecomposed for an indefinite time, and on adding to water, the alkali bicarbonate (potassium bicarbonate is preferably used) attacks the basic magnesium hypochlorite, forming a hypochlorite solution. As this reaction takes place at a continually decreasing velocity, the content of available chlorine, after a short time, tends to remain constant, for the loss due to spontaneous decomposition is partly counterbalanced by the generation of a further quantity of soluble hypochlorite. In the first of two examples dry sodium bicarbonate is mixed with one-third of its weight of basic magnesium hypochlorite, and in the second, this mixture is agitated with water. (Br. Pat. 147,535—1919. G. KERESZTY and E. WOLF, Budapest, Hungary, Oct. 6, 1920.)

Disinfecting Air.—Air is disinfected by passage through a packed tower in counter-current to a solution of ozone in water containing substances serving to increase the solubility of the ozone and to bind it in solu-

tion, prepared according to the process described in German Specification 297,335. The solution, after use, is treated with ozone in a second tower so that it may be used again and the process rendered continuous without the addition of further fresh solution. A portable apparatus may be used and the treated air is stated to be free from ozone and to be suitable for use in the treatment of wounds and of diseases of the breathing-organs. (Br. Pat. 147,566—1919. A. WOLF, Berlin, Oct. 6, 1920.)

Treating Textile Materials.—Textile fibers, such as wool, hair or other animal fibers, cotton, linen or other vegetable fibers, are mixed with a cellulose solution adapted to be converted into artificial silk by treatment with water, acids, ammoniacal copper oxide, zinc chloride or other suitable substances. Artificial fibers may be mixed with a cellulose solution of different composition. A solid mass is thus produced in which fibers are distributed. The fibers may be added while the artificial silk is being formed. The mixture may be allowed to dry in mass and may be reduced by cutting or otherwise to threads, bands, films or non-coherent fibers which may be spun, or the mixture may be molded into cord-shaped masses which may be comminuted to obtain fibers suitable for spinning. The mixture may be forced through tubes and on being introduced into a fixing agent may be drawn out to form threads or films. Bands or films may be formed by mechanical pressure and then treated with fixing agent and dried, the dry films, bands and threads being reduced to spinning fibers by well-known comminuting methods, or the bands may be twisted direct. (Br. Pat. 147,585—1919. E. CLAVIEZ, Adorf, Germany, Oct. 6, 1920.)

Utilizing Waste Rubber.—To recover textile material in a form suitable for spinning or paper making and rubber from waste rubber fabric, such as old cycle or motor tires, the fabric is cut into coarse fragments and treated with solvent under the influence of heat in a closed drum. The fragments are kneaded or agitated mechanically in the solvent until the whole of the rubber has passed into solution. The rubber solution is then run off and distilled to obtain the rubber, and remaining fragments of textile material washed with a fresh lot of solvent, which may be used afterward to treat the next charge. (Br. Pat. 147,628—1919. F. WAITZ, Bremen, Germany, Oct. 6, 1920.)

Preparation of Zinc Sulphide.—Anhydrous zinc sulphide is prepared as described below from the hydrated sulphide obtained by treating zinc hydroxide, heated to 90 to 100 deg. C. by means of steam, with sufficient sodium sulphide. The resulting caustic soda is decanted off and is used to prepare a fresh amount of zinc hydroxide from zinc sulphate. Periodically it is necessary to purify the caustic soda by crystallization and to reject the mother liquor which becomes charged with impurities. The precipitation of the zinc hydroxide is performed hot, to avoid the formation of a gelatinous product of low density, and the sodium sulphate simultaneously produced is used to prepare barium sulphate and sodium sulphide from barium sulphide. The latter is obtained by the reduction of barium sulphate by means of carbon, thus completing the cycle in which zinc sulphide and precipitated barium sulphate are obtained from zinc sulphate, barium sulphate and carbon. The hydrated zinc sulphide after being washed free from alkali is filtered and dried at 100 deg. C. or in a

vacuum. It is then mixed with sulphur and heated to 450 to 500 deg. C. in a muffle furnace, thereby volatilizing any cadmium sulphide, and is allowed to cool with exclusion of air. To prepare a lithopone, the precipitated barium sulphate after washing and drying is mixed with the desired proportion of zinc sulphide in an iron revoluble horizontal cylinder and finally passed through a fine sieve. (Br. Pat. 147,658—1919. J. DE COPPET, France, Oct. 6, 1920.)

Preparation of Hydrofluoric Acid.—Hydrofluoric acid is prepared from sulphuric acid, preferably in the form of monohydrate, and a natural fluoride such as fluorspar by thoroughly mixing equivalent quantities of the two substances with a solid such as finely-ground anhydrous calcium sulphate and heating to 200 to 300 deg. C. By feeding the material into a muffle furnace of the Mannheim sulphate type which is provided with mechanical stirring and discharging devices, the process becomes continuous and the handling of the resulting calcium sulphate charged with hydrofluoric acid is avoided. The hydrofluoric acid may be collected as such, or it may be absorbed by means of alkalis, thereby yielding alkali fluorides. The residual calcium sulphate is used in the preparation of fresh charging material. (Br. Pat. 147,711—1919. VEREIN CHEMISCHER FABRIKEN, Mannheim, Germany, Oct. 6, 1920.)

Oxidizing Oils.—In the oxidation of oils by exposure to oxygen, air or other gas containing oxygen a large reacting surface and easy separation of the viscid or solid product is obtained by mixing the oil with a dispersive medium or diluent that melts at a lower temperature than the product and so is separated by pressure or by centrifuging, or with one from which the product is separated by dissolving out the diluent or the product. Accelerators of the reaction, such as lead or manganese compounds of resinous acid or other siccatives may be added, and linoleum cement may be made directly by addition of gum kauri, colophony or other matters usually added to the oxidized oil. Dispersives or distributors mentioned are neutral or basic salts, such as sodium sulphate or chloride, which are removed from the finished product by washing with water, and tallow, Chinese tallow, paraffine wax, ceresine, stearine, colophony and fully hydrogenated sunflower oil, which are melted to dissolve the oil, the solution being then sprayed or allowed to set and crushed or scraped to obtain a fine powder; or a porous form is obtained by blowing in air during setting if this porosity is not formed naturally. In an example, 750 kilos completely hardened sunflower oil, 22.5 kilos of manganese resinate, and 250 kilos of linseed oil are melted together, allowed to set, powdered, turned over mechanically for about eight hours, melted and pressed. In another, 650 kilos sodium sulphate and 350 kilos train oil are mixed and treated with a current of air in a rotary drum that may be heated up to 110 deg. C. until oxidation is complete. The sulphate is removed by lixiviating with water, or the oxidized oil is extracted by a solvent. In a third example, 800 kilos perfectly hardened sunflower oil, 200 kilos linseed oil and 6 kilos manganese resinate are melted, and air is driven into the mixture as it sets until it is pasty. It is then poured into molds and the porous slabs allowed to stand for twenty-four hours, melted and pressed. (Br. Pat. 147,661—1919. G. SCHICHT AKT. GES., Aussig, and A. EISENSTEIN, Leitmeritz, both in Czechoslovakia, Oct. 6, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Minerals Separation Loses Its Appeal

On Dec. 9 the Circuit Court of Appeals in Philadelphia handed down an opinion in which it most fully sustained Judge Morris' several orders, by which the District Court in Wilmington had dismissed several applications of Minerals Separation of various supplemental bills, in which it sought to have the Miami Copper Co. found in contempt of court and enjoined from continuing to operate its present flotation methods.

Minerals Separation had appealed these orders upon the ground that the District Court had erred in refusing injunctive relief by virtue of its orders of July 23, 1920, and as interpreted and supplemented by an opinion filed July 29, and an order of the court entered Aug. 11, 1920. (See CHEM. & MET. Eng., Aug. 11, 1920, pp. 221 and 254.)

The Circuit Court of Appeals finds that the trial court did exercise its discretion as to proceedings in contempt, and as it held "that the facts set up by the petition are not of the character required to sustain a judgment in contempt," the present opinion infers that the District Court evidently meant that the modification or changes were not plainly mere colorable equivalents of the procedures found to infringe, and that it did not abuse its discretion, adding, "He arrived at the same conclusion at which we would have arrived if we had been in his place."

The opinion of the Circuit Court of Appeals goes thoroughly into the questions as to whether the trial judge rendered his judgment upon a wholly wrong comprehension of the facts or the law, and whether, accordingly, he abused his discretion, "the only respect in which an appellate court will disturb such an order."

This opinion not only most positively asserts that the trial judge has not made any of these errors, but, in ending, adds: "We would have made the same disposition of the case had we been sitting in the District Court."

Conference Committee to Hold Hearings On Patent Office Bill

Plans were perfected on Friday, Dec. 10, for a conference immediately after the holiday recess of Congress on the Nolan Patent Office bill. Contrary to the usual custom, the Conference Committee will conduct hearings, at which further testimony in regard to the bill will be taken.

Section 9 of the Nolan bill adds to the measure the bill originally drafted by Dr. F. G. Cottrell authorizing the Federal Trade Commission to administer patents granted to Government employees. There is considerable opposition to section 9 and it is understood that Dr. Cottrell, Dr. Andrew Stewart and other proponents of the section are unwilling to have it jeopardize the remainder of the Patent Office bill.

Senator Norris, chairman of the Committee on Patents of the Senate, and Representative Nolan, chairman of the Patents Committee of the House are not inclined to eliminate section 9, it is reported.

Meeting California Section, A.C.S.

The annual meeting of the California Section, A.C.S., was held on Dec. 3 at the Engineers' Club in San Francisco. Officers were elected for the ensuing year as follows: Chairman, Dr. W. C. Bray; vice-chairman, B. S. Drake; secretary-treasurer, L. W. Chapman; councillors, Dr. L. H. Duschak, R. A. Gould, Dr. Joel Hildebrand and Dr. R. E. Swain.

Two interesting papers were presented. Prof. S. W. Young of Stanford University discussed the efficiency of the various laboratory types of still-heads used in fractional distillation and described a new type by which it is possible to obtain increased efficiency.

Ludwig Rosenstirn, of the Great Western Electrochemical Co., reviewed the history of the chlorine industry and its relation to the alkali industry, discussing the present status and the effect of the development of the electrolytic process for the production of chlorine and its compounds upon the chemical processes; thus pointing out the importance of a thorough understanding of related industries in the successful conduct of present-day chemical manufacturing.

To Try to Pass Dye Bill

After a conference among those interested in the dyestuffs tariff bill, held in the office of Representative Longworth of Ohio, it was decided to make every effort to secure tariff legislation on dyestuffs at this session of Congress. It was stated at the conference that the failure to enact tariff legislation is having a most untoward effect on the dye industry. Unless this legislation is obtained promptly it was predicted that all but the low-cost producers would be forced to suspend operations. Senator Watson, the acting chairman of the Finance Committee of the Senate, is willing that the dye bill be taken up at the earliest possible moment. Due to the fact that the appropriations bills have right of way and to the fact that there is very determined opposition to the dye bill now on the calendar, it would not be difficult for its enemies to prevent its enactment.

Chlorine May Have Therapeutic Value

The fact that workers in the chlorine cell room at Edgewood Arsenal have been singularly free from any diseases of a pulmonary or bronchial type leads officers of the Chemical Warfare Service to believe that this gas has therapeutic properties. This fact was first noted during the influenza epidemic. Outside of the chlorine room there were numerous cases of influenza, in some rooms amounting to one-third of the number employed. There was not a case in the chlorine room. Since that time the matter has been a subject of some observation, but no technical study has been made of that particular property of the gas. The belief that the gas may have this value is strengthened by the report of the Surgeon General of the Army showing that practically none of the gas casualties were followed by tuberculosis.

Mechanism of Catalytic Processes

A meeting which brought together the New York Sections of the American Chemical Society, American Electrochemical Society, Société de Chimie Industrielle and the American Section of the Society of Chemical Industry was held in Rumford Hall Friday evening, Dec. 10.

A letter from Dr. Parsons conveying to the Section the resolution and recommendation adopted by the Committee on National Policy in regard to the Nolan Patent Office bill was read by the secretary.

Officers of the New York Section, A.C.S., for 1921 were elected as follows: Chairman, John E. Teeple; vice-chairman, Martin H. Ittner; secretary-treasurer, Herbert G. Sidebottom; executive committee, D. W. Jayne, C. H. Herty, C. A. Browne, R. H. McKee.

Dr. Parsons then called attention to the position of the dye bill. It is highly important, he said, that action should be taken during this session of Congress, as the passage of a peace resolution in the spring will jeopardize the dye industry unless protection is assured. Members were asked to send telegrams or to write to their Senators urging immediate action.

MECHANISM OF CATALYTIC PROCESSES

Prof. Hugh S. Taylor of Princeton in a paper on "The Mechanism of Catalytic Processes" reviewed the theories which have been advanced in explanation of the phenomena of homogeneous and heterogeneous catalysis and presented the results of research designed to test experimentally the rival hypotheses.

HOMOGENEOUS CATALYSIS

While examples of homogeneous catalysis—such as the hydrolysis of esters and the inversion of cane sugar—have been known for many years, few attempts were made to study the mechanism of the process until comparatively recently. A constantly increasing mass of evidence points toward the formation of intermediate compounds as being the correct explanation. Thus in the case of ester hydrolysis, ester and acid form a binary compound which in turn unites with water to form an unstable ternary complex, capable of breaking down to form either the original substances or the reaction products of hydrolysis. It has been demonstrated that aqueous solutions of an ester and an acid contain definitely measurable quantities of such complexes. A very recent theory involving the absorption of infra-red radiations has not been satisfactorily studied from an experimental point of view.

During the war there was in some European countries a simultaneous demand for fats and glycerine. By the application of homogeneous catalysis it was found possible to replace the glycerine in fats by mannitol and thus obtain both fat and glycerine. The possibilities of such ester exchange are but little realized.

HETEROGENEOUS CATALYSIS

Four theories as to the mechanism of heterogeneous or contact catalysis have received careful consideration. Taking the hydrogenation of unsaturated compounds in the presence of nickel as an example, the theories may be summarized as follows:

Sabatier believes that the nickel forms a hydride which then reacts with the unsaturated compound.

Bancroft believes that there is selective adsorption

of the reaction products but admits that this hypothesis fails to explain the increased yield of ethylene obtained when steam is mixed with alcohol vapor before being passed over alumina.

Armstrong maintains that the nickel forms a loose complex with the carbon-containing substance, which then reacts with the hydrogen.

The effect of infra-red radiations is held by Lewis to account for the adsorption of hydrogen by nickel, the hydrogen molecule dissociating in the presence of these radiations to form hydrogen atoms.

EXPERIMENTAL INVESTIGATION

In order to get at the facts, Prof. Taylor devised a series of experiments to test out the following reactions:

A glass tube containing nickel precipitated on Nonpareil brick was evacuated and the amounts of nitrogen, hydrogen, carbon monoxide, carbon dioxide and ethylene required to fill the tube at different temperatures were carefully measured. Plotting temperature as abscissa and c.c. of gas as ordinate, some very interesting curves were obtained. Nitrogen which was used as the reference gas gave a line approaching the temperature axis with increasing temperature. CO₂ and H₂ gave lines lying above the N line in the order given, and parallel to it. Since CO forms nickel carbonyl at low temperatures and decomposes into CO₂ and C at high temperatures, only one point could be obtained on this curve (175 deg. C.), but this was above the curve for H₂. Similarly C₂H₄ gave a point still higher at 175 deg. C. This would indicate that Ni adsorbs C₂H₄ in preference to H₂.

In similar experiments with copper, the H₂ and CO₂ lines were found to coincide with the N₂ line within the limits of experimental error, while CO and C₂H₄ were markedly adsorbed at low temperatures. At higher temperatures these curves also coincide with the N₂ curve.

Further studies with mixtures of these gases have led to the conclusion that a bimolecular reaction in the gas phase may become a monomolecular reaction on the surface of the catalyst. The catalytic oxidation of SO₂ to SO₃ is an example of this phenomenon. With high concentrations of SO₂ and O₂ the reaction is not termolecular as required by the law of mass action, but toward the end of the reaction series the reaction does become termolecular.

Experiments are now being made using the reaction products of equations 1 to 5 where these have not already been studied.

C.W.S. Asks for \$4,457,376

Congress has been asked by the Secretary of War to appropriate \$4,457,376.20 for the Chemical Warfare Service during the coming fiscal year. Approval was not forthcoming for twice that amount, which General Fries had estimated for the thorough conduct of the work of the next year. This curtailment of the appropriation will limit greatly the plans for quantity production of gas masks. In addition \$35,000 is asked for the maintenance of Chemical Warfare Service schools.

Bureau of Standards Appropriations

Among the appropriations asked by the Bureau of Standards for use in pursuing its work during the next fiscal year are the following:

For metallurgical research, including alloy steels; properties of aluminum alloys; development of metal substitutes; investigation of new metallurgical processes, \$70,000. This is an increase of \$45,000 over the current appropriation.

For apparatus, machinery, appliances, laboratory supplies, furniture for laboratories and cases for apparatus, \$90,000. Increase, \$15,000.

For testing varnish materials, soap materials, inks and chemicals, \$50,000. Increase, \$20,000.

To develop color standards and methods of manufacture and of color measurement, with special reference to their industrial use in standardization and specification of colorants such as dyestuffs, inks and pigments, \$12,000. Increase, \$2,000.

To study methods of measurement and technical processes used in the manufacture of pottery, tile and other clay products \$35,000. Increase, \$10,000.

For the investigation of the problems involved in the production of optical glass, \$40,000. Increase, \$15,000.

To investigate textiles, paper, leather and rubber in order to develop standards of quality and methods of measurement, \$40,000. Increase, \$25,000.

For the standardization and design of sugar-testing apparatus, \$10,000. Increase, \$10,000.

High-temperature measurement investigation, \$15,000. Increase, \$5,000.

To determine experimentally important physical constants of materials, \$25,000. New appropriation.

For purchase, preparation and distribution of standard materials to be used in checking chemical analyses and in the testing of physical measuring apparatus, \$15,000. This is a new appropriation.

For investigation of the problems involved in the electro-deposition of metals, \$15,000. New appropriation.

For the equipment, maintenance and operation of a low-temperature laboratory and the production of liquefied gases, \$15,000. This is a new appropriation.

For an investigation of radio-active substances and the methods of their measurements and testing, \$15,000.

Tariff Hearings Begin Jan. 6

So as to expedite the revision of the tariff, the Ways and Means Committee of the House of Representatives plans to complete its hearings during the present session of Congress, so that the bill may be drafted and its consideration begun promptly after Congress meets in extra session.

Schedule A, which consists of chemicals, oils and paints, will be the first one taken up. Jan. 6, 7 and 8 will be devoted to hearing testimony as to the need of revision of the tariff covering commodities under those heads. Schedule B, which consists of earthenware and glassware, will be considered at the hearings Jan. 10 and 11. The metal schedule is to be considered Jan. 12, 13 and 14. Sugar and manufactures thereof is scheduled for hearing Jan. 18 and 19.

Consulting Chemists' Appointments Approved

The Secretary of War has approved the appointment by General Fries of the fifteen members of the American Chemical Society's advisory committee as consulting chemists of the Chemical Warfare Service.

Personal

Dr. J. F. CARLE, until recently chief chemist at U. S. Nitrate Plant No. 2, Muscle Shoals, Ala., resigned from the Nitrate Division on Nov. 1 to become president of the Southern Testing Laboratories, with headquarters at Birmingham, Ala.

Colonel C. W. EXTON, who recently was transferred to the Chemical Warfare Service, to take charge of the training section, has been designated as assistant chief of the Chemical Warfare Service.

T. G. HAGEMAN, formerly chief engineer of Norsk Hydro-Elektrisk Kvaestofaktieselskab (Norwegian Hydro-Electric Nitrogen Co., Ltd.), Christiania, Norway, has started his own business as a consulting engineer for the nitrate industry. His office address will be Ths. Heftyes gate 44, Christiania.

ROBERT B. HITCHCOCK has resigned his position as chief chemist at the coke plant of the Youngstown Sheet & Tube Co., Youngstown, Ohio, to accept a similar position with the Woodward Iron & Steel Co., Woodward, Ala.

FREDERICK P. KEPPEL is on his way to Paris to take up his work as American Administrative Commissioner at the headquarters of the International Chamber of Commerce.

Dr. R. B. MOORE, chief chemist of the Bureau of Mines, announces the selection of the following staff for the cryogenic laboratory which is to be conducted at the Bureau of Mines under his supervision: JOHN W. DAVIS, mechanical engineer; C. W. SEIBEL, chemist, and Dr. LEO FINKLESTEIN, chemist. Mr. Davis has been connected with the faculty of the Leland Stanford University, Mr. Seibel with that of the University of Kansas, and Mr. Finklestein with the University of Chicago.

E. C. MORSE, director of sales, War Department, is terminating his connection with the Government on Dec. 31, and for his work in connection with disposing of the hundreds of millions of dollars of surplus war stock has been awarded the Distinguished Service Medal, which was presented to him by Secretary of War Baker in the latter's office in Washington on Dec. 7.

BENJAMIN SCHNEIDER, of Drydenforth, Lee, Thritton & Wiles, spoke before the Chicago Chemists' Club on Dec. 7 on "The Law of Secret Processes."

At the annual meeting of the American Engineering Standards Committee held in New York on Dec. 4 A. A. STEVENSON, a representative of the American Society for Testing Materials, was re-elected chairman for 1921, and GEORGE C. STONE, a representative of the American Institute of Mining and Metallurgical Engineers, was re-elected vice-chairman.

Obituary

REGIS CHAUVENET, president emeritus of the Colorado School of Mines, Denver, and widely known throughout the country as a chemist and metallurgist, died on Dec. 5. He was seventy-eight years old.

GUSTAVE DROBEGG, a consulting chemist and a director of several dye manufacturing companies, died in the Swedish Hospital, Brooklyn, N. Y., on Dec. 6 in his sixtieth year. Mr. Drobegg had been connected with the firm of Charles Pfizer & Co. in Manhattan and Brooklyn for twenty-five years and was one of the most prominent men in the work of creating the American dye industry during the war. He was a native of Coblenz, Germany, and studied chemistry at the University of Munich. He was a member of the

Chemists' Club, Society of Chemical Industry and other societies.

EDWARD HERMS of North Tonawanda, N. Y., passed away on Nov. 4, after a prolonged illness with heart trouble. For a number of years he was chemist for the Commonwealth Steel Co., St. Louis, Mo., then superintendent of the Strong Steel Foundry, Buffalo, N. Y., superintendent of the open-hearth department of the Pittsburgh Steel Foundry and at the time of his death was employed as chemist of the Buffalo Bolt Co., North Tonawanda, N. Y.

ERNEST MCAULAY, manager of the Mines & Smelter Supply Co., El Paso, Tex., died on Nov. 20.

Book Reviews

THE MODERN ELECTROPLATER. By *Kenneth M. Coggeshall*. New York: Norman W. Henley Publishing Co. Price \$3.

The actual work that is being done by the electroplater of today is too little understood and a story of the "Modern Plater" would make interesting reading. The author fails to keep to his subject, and shows that he is not in touch with and even discredits the knowledge and ambitions of the modern plater when he states: "It is not necessary that an electroplater be a careful student of either electricity or chemistry. A technical discussion of laws relating to electrochemistry would undoubtedly have but little interest for even an expert plater." He is consistent, however, as he measures up to his own foot-rule when he endeavors to discuss the technical or practical part of electroplating, standing on tiptoes to keep his head above water.

The modern plater is growing beyond "rule-of-thumb" methods, regulation of amount of metal deposited by the voltage and trying to determine the metal and chemical content of a plating solution with a hydrometer all of which are recommended in this book.

The author has been a careful student of trade catalogues, and gives in brief the story of what is needed in a plating and polishing room which may be of interest to a novice. The practical part offers nothing but what is generally known and with some of which the author is just about on speaking terms.

Silver can be and is deposited with a current density of 5 amp. per sq.ft., which is twice the rate given, and when a silver "strike" is used, "The work is (not) dipped for a moment in a hot potash bath and then transferred, without rinsing, to the 'strike' solution" (p. 185). Even a "careful student" would soon get into trouble if that method was followed.

For making a nickel solution a definite formula is recommended: Water, 1 gal.; nickel ammonium sulphate, 14 oz.; boric acid, 2 oz., and then it is recommended that "The nickel ammonium sulphate is dissolved in hot water, then a quantity of the latter is added to the solution until a hydrometer reading shows a density of about 7 deg. Bé." The author probably does not mean boric acid by "the latter." Fourteen ounces of nickel ammonium sulphate in a gallon of water will give the density of 7 deg. Bé. That is above the point of saturation at ordinary plating room temperature during the winter months, and crystallization will result.

That aluminum is violently attacked by a caustic alkali is well known, and the author is incorrect in stating, "Aluminum wire baskets or trays, for example, are affected to some extent by both potash and muriatic acid . . . and are nevertheless quite popular . . ." Aluminum baskets can be used in "bright dips" but not in "potash" solutions.

Common high brass, such as is commercially used, generally consist of about 64 per cent copper and 36 per cent zinc and not 60-40 (p. 163). Gold when alloyed to make any carat is not alloyed with copper alone (p. 172).

In "A Manual of Electro-Metallurgy," James Napier, 1853, it is stated that the electroplating of iron with zinc from a zinc sulphate and a zinc cyanide solution was done

at that time, yet the author states, "Until recently a process known as hot galvanizing was employed in all instances where this film of zinc was required."

Nothing of any value has been added to modern electroplating practice in bringing out this book, and it will soon take its place among those of which there are now already too many.

GEORGE B. HOGABOOM.

Current Market Reports

The Chemical and Allied Industrial Markets

New York, Dec. 13, 1920.

The chemical market showed flashes of activity during the past week and it was apparent that the prolonged period of readjustment has brought the industry into a healthier position. Inquiries from northern Europe were noted in more volume of leading chemicals, although domestic consumers still showed the same conservatism in their operations. Several interests close to the pulse of trade asserted that the new year will occasion a renewal of buying activity. They are consequently looking forward to its advent. When business assumes normal dimensions there will be a lack of inflation and prices will adhere more to the law of supply and demand than at any time in recent years.

Small sales of *zinc sulphate* are reported to tanneries, textile mills and paint factories, but business has shown no real punch of late. Producers hold carload lots at 3½c. per lb. and smaller quantities up to 4c. per lb. Factors in *zinc chloride* are booking business in the granular grade at prices ranging from 12c. to 14c. per lb., the inside figure being for carlots. Fused material is bringing 9@11c. per lb. according to quantity. *Sulphite of soda* producers report sales of crystals at 4c. per lb. in large quantities and up to 4½c. per lb. in smaller lots. Moderate inquiries were reported.

Large sellers of *carbonate of potash* quoted the market at 12½c. per lb. spot for the 80-85 per cent grade in large lots and 13c. per lb. in smaller quantities, with only quiet trading. Supplies appear fully adequate to take care of prevailing inquiry.

Some sales of *arsenic* were reported to manufacturers of insecticides, but the principal movement at present is against old contract orders. Small lots of white powdered are on the market at 12@13c. per lb. The red variety is quoted by producers at 15c. per lb. Dealers reported sales of *bleaching powder* for domestic consumption at 3c. per lb. f.o.b. New York. Resale material at the works was quoted at the same figure. The movement has remained quiet since the recent sharp decline of this article. A feature of the market was the brisk trading noted in *oxalic acid*. Surplus spot stocks on the market have been entirely cleaned up and leading factors were quoting prices ranging from 19c. to 21c. per lb. All indications point to a strong market with fluctuating prices.

Supplies of *peroxide of soda* continued scarce and the market is quoted firm at 35c. per lb. Producers are not very eager to quote at present and the only quotations heard are from dealers. Spot *bichromate of soda*, standard brands, was generally quoted at 9½@10c. per lb. December shipments of resale stock were quoted at 9½c. per lb. f.o.b. works. The tone of the market remained quite steady.

COAL-TAR PRODUCTS

The coal-tar products market is slowly but surely approaching the period where a strong demand must take the place of the present stagnancy. While there is not very much indication on the surface to warrant such a condition, there is, nevertheless, an undercurrent of feeling in many quarters that point to a much better business shortly after the first of the year. Color manufacturers are steady in their views on an improvement in the demand over next year and while prices are sagging in their industry through the natural law of lack of demand at this time, opinions seem to be of a more optimistic nature. The situation as regards

a steady supply of crude products seems good as to raw material, coal and working conditions at the various plants.

Consumers are showing very little interest in *xylene* at present and only routine trading is heard with figures quotably unchanged at 45@50c. per lb. There are not many sources of supply on *monochlorbenzene*, although the market is said to be fairly easy on supplies at a range of prices from 17c. to 18c. per lb. Producers stated that a limited quantity is moving into various consuming channels.

A slightly better demand for *aniline oil* was reported in some directions, although sales were confined mostly to small quantities. Supplies are plentiful in second hands with prices ranging from 24c. to 26c. per lb. Manufacturers are still quoting 28@30c. per lb. and are waiting for a real demand to set in. The *aniline salts* market is quiet in all quarters. Producers are firm in their views and quote 32@34c. per lb., depending on quantity. Very little *benzidine base* is moving into domestic channels, where there is some inquiry reported from foreign consumers. Available supplies of the base and sulphate material are quoted at \$1.05@\$1.15 per lb. Factors in the *dimethylaniline* market find the call reduced to a minimum. A fair amount of supplies is available, but no heavy offerings are noted. Prices range from 70c. to 85c. per lb., depending on seller.

GROWTH OF THE COAL-TAR INDUSTRY

A recent report of the United States Tariff Commission stated that the production of coke and the byproducts obtained from coal distillation in 1919 showed a slight decrease in the amount of tar distilled and a large decrease in the output of pure benzene and especially of pure toluene. A great significance is attached to the future of the coal-tar industry in the fact that the productive capacity of byproduct coke ovens in the United States increased over 17.2 per cent during 1919. There is no doubt that, with the exception of anthracene, sufficient supplies of the basic materials of coal-tar origin will be available from American sources for the growth of the industry.

Considerable progress has been made during the past year in the case of anthracene, but the problem of securing adequate supplies is still unsolved. In 1919 the output was three times as large as in 1918, or about 800,000 lb., and a much larger quantity was refined than in 1918. Although this showed a greater and more encouraging progress, a larger increase in output must be secured before there will be enough American anthracene available to supply the dye industry. It is believed that the 1919 production of crude anthracene contained less than one-quarter the amount which would be required to supply the American demand. The real difficulty is not primarily an actual lack of anthracene in the tar or purely technical difficulties, but rather the fact that its removal leaves the pitch so hard that it does not find a ready market under American conditions.

PRODUCTION OF INTERMEDIATES

As was expected, there was a sharp decrease in the output of several intermediates needed primarily for explosives. The most noticeable case was phenol, which showed an enormous production—100,000,000 lb. in 1918—but fell to less than 1,500,000 lb. in 1919, nearly all of this being obtained from coal tar. Another example was the case of *monochlorbenzene*, which had an output of 20,000,000 lb. in 1918 and 4,000,000 lb. in 1919. There was also a considerable decrease in several intermediates required for making dyes used for army uniforms. For example, there was a marked decrease in the output of *metatoluylenediamine*, which was used for making a khaki dye for cotton uniforms, and a tremendous drop in *metanitriline*, which was used for making a khaki dye for wool uniforms.

A comparison of the intermediates produced in 1918 and 1919 shows a considerable increase in the number of intermediates. In 1919 there was almost twice as many different intermediates produced as in 1918. Intermediates which had a strong demand and whose manufacture had been well established by 1918 showed comparatively little change in 1919. Nitrobenzene gained about 10 per cent, the 1919 output amounting to about 42,000,000 lb. Aniline production

was about 25,000,000 lb., a gain of 1 per cent. The output of U.S.P. benzoic acid increased from about 175,000 lb. in 1918 to over 600,000 lb. in 1919, with a drop in price from \$3 per lb. to 75c. per lb. Orthotoluidine increased from 650,000 lb. in 1918 to a little over 1,000,000 lb. in 1919. The general increase in the output of intermediates derived from toluene is due to relaxation of the restriction in the use of toluene during war times. Progress among anthracene derivatives is of special interest. In 1919 there were ten intermediates derived from anthracene, against only five in 1918. The output of anthraquinone, which is the most important, because it serves as raw material for the manufacture of nearly all other intermediates derived from anthracene, was about ten times as great in 1919 as in 1918.

VEGETABLE OILS

The market on vegetable oils remained quiet and has shown no tendency of firmness for the past few weeks. Trading was practically of a hand-to-mouth nature. Resale offerings of *coconut oil* on the Coast brought out sharply lower prices for manila oil. Offerings were heard at 10c. per lb. sellers' tanks, December shipment, and 10½c. per lb. January shipment. Ceylon grade oil was offered in barrels at 13½c. per lb. New York. The market for *corn oil*, crude, held around 9½c. per lb. with no business being reported. Oriental *peanut oil* was easier and sellers called for bids around 8½c. per lb., sellers' tanks, December shipment from the Pacific Coast. Buyers' ideas were about ¼c. under this basis.

Buyers and sellers were apart from their views on *soya bean oil*, with the result that no business was placed. December shipment from the Coast closed at 6c. per lb. January-March shipment closed at 6½c. per lb. sellers' tanks, f.o.b. Pacific Coast. The spot market was nominal at 9½c. per lb., no sales being reported. The market for *cottonseed oil* was a featureless affair, demand being only of a moderate nature. Prime summer yellow was quoted at 9½c. per lb., with only small inquiries noted for European ports. Crude oil held at 6½c. per lb. f.o.b. mill.

The Chicago Market

Chicago, Dec. 8, 1920.

It seems there is no degree of quietness to which the chemical market can attain which is not immediately outdone by more pronounced quiet. The fact is that the past ten days have been more excessively dull than any foregoing period in the year. On all hands production has been curtailed and yet demand does not absorb supply. Low prices seem to have no attraction and normally heavy buyers content themselves with small routine purchases, ignoring opportunities to stock up at prices which, a few weeks ago, would have looked like real bargains.

The attitude of consumers is that anything is possible in regard to prices in the immediate future and they are going to stay out until the market is stabilized. Bona fide buyers are able to get goods at practically their own terms and nothing like heavy buying is seen in any line.

HEAVY CHEMICALS

A lowering in price on various items and a lack of interest on the part of all buyers are outstanding features of the past two weeks. Sales of *bleaching powder* have been reported as low as 2½c. per lb. and offers at around 3c. for spot goods are plentiful. Some future business is reported at 3½c. *Caustic soda* is likewise hard to sell, 4c. being the prevailing price on the small lots going. Stocks are light but demand is absent. Bottom is being approached on *soda ash*, offers at \$1.85 failing to produce business. Buyers could probably secure concessions from this figure. *Sul soda*, held at \$2 per 100 lb., is quiet.

Alcohol, with prices firm, is experiencing a lack of demand. Ethyl grade, 190 proof, is quoted at \$5.15 per gal.; methyl grade, 97 per cent, at \$1.95, and denatured, 96 per cent, at 85c. Holders of resale stock show a disposition to shade these prices. Depression in consuming trades is weakening this market. Output of *glycerine* is remarkably light, but at that is more than equaling demand. The c.p.

grade, less drums, has changed hands in small quantities at 18c., and dynamite grade is offered at 17c.

Low prices prevailing in the copper market have carried *blue vitriol* down to \$6.75@6.85 per 100 lb. for 99 per cent grade, which prices are firmly held by a good demand. *Salt cake*, with consuming demand steady, holds firm at \$31 per ton. *Ammonia* is weak and uncertain, small lots only being taken at from 10@11c. per lb. for 26 degree. Producers' quotations are unchanged.

The acid market, in common with other chemical lines, shows lack of interest. *Sulphuric* is off in price as well as demand, 66 degree being offered at \$22 per ton. Some transactions are reported at \$1@1.50 below this figure. *Nitric*, in a dull market, is offered by producers at \$7.75@8 per 100 lb. for 42 degree. The fact that Government supplies of *carbolic acid* are held at 12c. per lb. has had no effect on the market, sales from stock being made at from 7@7½c. per lb. Plentiful supply is available. Business in *acetic acid* is dull, the glacial being offered at 10c. and the 28 per cent at \$3 per 100 lb. in barrels.

VEGETABLE OILS

While the trading in *flaxseed* has been stimulated somewhat by bullish reports from Argentina, no effect has been felt in the *linseed oil* market. Low prices are not operating to stimulate demand, business being practically confined to small lots. It would seem as though the bottom had been reached, as bulk is offered in tanks as low as 70c. per gal., with but few takers. Oil in barrels, carload lots, is 77c., and dealers are selling 1- to 5-bbl. quantities of stock at 97c.

Cottonseed oil, offered at 6c. per lb. in sellers' tanks at point of production, is a drag on the market. Consuming demand is notable for its weakness and prime summer yellow, offered in tanks, delivered, at 7c. per lb., has few takers. *Coconut oil*, Manila variety, is offered f.o.b. Coast in sellers' tanks at 10½@11c. per lb. and the refined edible kind is quoted here at 16½c. in barrels. Curtailed production of *corn oil* has been equaled by lower demand, and recent transactions have passed at 6½c. per lb. in cars f.o.b. Chicago. The edible refined now brings 12½c. per lb. in barrels.

NAVAL STORES

Gradually lowered prices are still the feature in naval stores, notwithstanding the fact that the producing season is closing with stocks below normal. Demand is light, but dealers do not attribute recent price drops to this so much as to the habit naval stores prices have of taking a December slump. Curtailed activities on the part of consuming buyers have permitted a little drop in prices of *pine oil*, the pure steam distilled now being quoted at \$1.60 and the destructively distilled at \$1.50. *Rosin oil*, first rectified, is offered at 66c. and commercial *pine tur oil* at 47c. *Turpentine*, weak under poor demand, is quoted at 90c. per gal.

The St. Louis Market

St. Louis, Dec. 10, 1920.

The inactivity of heavy chemical demand has become even more pronounced here during the past two weeks and the amount of spot business has become negligible. New contract business has slowed up considerably also, but shipments on contracts still average close to normal, according to producers, and a good many contracts are being renewed. Producers report that consumers are buying only for their immediate needs and that their needs are being decreased materially by the depression in other lines. Little change in this situation is looked for before the first of the year and no impressive upturn is expected then. In spite of the quiet market producers are holding both spot and contract prices at the levels reported previously and feel that they will not be forced to alter them materially in the near future.

There is still some call for the 66 deg. *sulphuric acid*, this coming mainly from the oil fields where production and refining show no signs of slackening. Prices hold firm at \$22 per ton and 1½c. per lb. carload lots. Demand is slow for the 98 deg. sulphuric acid. A quotation of \$25 per ton f.o.b. works is being maintained. Inactivity marks the 60 deg. sulphuric acid market and producers are asking \$16.50

per ton and 1½c. per lb. in carboys. *Oleum* is slow at \$28.50 per ton.

Producers are still keeping their supplies of *muriatic acid* low, though demand has been very quiet, and prices are firm at 1½@2c. per lb. and \$25 per ton in bulk.

Sodium bisulphate (niter cake) is slightly more active than two weeks ago, with prices being maintained at \$7@8 per ton.

Both inquiries and orders for *nitric acid* continued to fall off, but producers report deliveries on contracts about normal. This is taken to mean that consumers' needs have not decreased materially, but that where they must re-enter the market for supplies they are buying from hand to mouth. Quotations are \$7 per 100 lb. for the 36 deg. test and \$10 per 100 lb. for the 42 deg. test. *Standard mixed acid* is quoted at 1½c. per lb. of sulphuric content and 11½c. per lb. for unit of nitric acid.

The Iron and Steel Market

Pittsburgh, Dec. 10, 1920.

In the past week the independent market on sheets has declined to the Steel Corporation or Industrial Board level: Blue annealed sheets, 10 gage, 3.55c.; black sheets, 28 gage, 4.35c.; galvanized sheets, 28 gage, 5.70c. Previously there had been similar reversions in tin plate, bars, shapes, plates and wire products. Of the important steel mill products pipe alone remains as presenting a higher market on the part of the independents than the Steel Corporation level. The exception is not especially important in itself, for the reason that the large delivery premiums formerly obtained by independents have practically disappeared, leaving the independent market on the regular independent list, which is only 3½ points or about \$7 a ton above the Steel Corporation schedule. The exception is of importance, however, in this respect, that alone of all steel products pipe is in good demand, with heavy requirements against contracts and a moderate amount of new buying. The pipe mills are comparatively busy, in general, while the leading interest has difficulty in meeting customers' requirements, although for two or three weeks past it has been shipping up to its loading capacity, or at about 30 per cent above production, which is substantially at capacity. During the period of car scarcity a stock was accumulated equal to about a month's production.

MARKET STAGNANT

The stagnation in the finished steel market continues. The price reductions by independents have had no appreciable effect, although it should be understood that there was no definite hope that much business would be developed, at least at the outset, by the reductions. The independent mills simply abandoned a position that had become untenable and that they knew would have to be abandoned some time.

The Steel Corporation continues to operate to the physical limit in nearly all departments. The supply of coal and coke has improved and a few additional blast furnaces have been blown in, so that the corporation is probably operating at a slightly heavier rate than a couple of months ago. The independents, on the other hand, have steadily dwindling operations. Not a few are closed entirely, though probably not permanently, as some orders may accumulate for a run of a week or two. Others are operating at 60 to 75 per cent, and the general average is probably under 50 per cent.

The independents having reduced their prices to the Steel Corporation level, the next point is whether they will shade the Steel Corporation prices. There seems to be practically no doubt that some of them will. The present stagnant market is no test, since there is no incentive to make special prices. The real test will probably come in January, when in the course of events there should be somewhat more buying. Buyers cannot indefinitely stay so completely out of the market as they are at present.

Inasmuch as common expectation is that there will be no full demand for steel for many months, sufficient to engage all the capacity, the question is discussed whether, or when, the Steel Corporation will itself reduce prices. At present it has well-filled order books, apparently sufficient to

enable it to maintain approximately the present rate of operation until some time in the second quarter of the new year. Judge Gary's statement three weeks ago today, to the effect that the corporation would not alter its prices, had the specific qualification "unless and until it becomes necessary and proper to make changes to meet altered conditions." The immediate bearing was that the corporation would not advance its prices, as for a long time the independents had hoped, but it is plain that if demand for steel remains light for a period of months there is a prospect of business in general undergoing such a general readjustment that the corporation's costs will be reduced, and that would furnish a basis for reduced prices. As long as the corporation was operating at a much higher rate than the independents it would hardly reduce prices because of price cutting by independents. With a fair operation the Steel Corporation prices should prove quite profitable, unless to independents who have saddled themselves with extra costs during the period when prices were so high that costs were a minor consideration. It must be remembered that the Steel Corporation's total profits have been much larger than the net earnings reported, by reason of various heavy deductions and allowances being made for contingencies.

SEMI-FINISHED STEEL

There is no market at all in semi-finished steel, and prices are altogether nominal. It is assumed that if any important business were offered some at least of the independents would meet the Steel Corporation prices of \$47 on sheet bars and \$57 on rods, these prices being \$5 above the Industrial Board schedule by reason of advances the corporation made in August and September. The corporation does not seem to have advanced its billet price above the \$38.50 figure of the Industrial Board schedule, and there is no doubt that no independent would name that price. In some quarters it is doubted whether the corporation will continue its present prices on sheet bars and rods, there being a possibility of its going back to the old prices.

NOVEMBER PRODUCTION

The thirty companies making monthly reports for their ingot production to the American Iron and Steel Institute showed an output in November of 2,638,670 tons, against almost precisely 3,000,000 tons in each of the three preceding months. All four months had twenty-six working days each. The report shows a decrease of 13 per cent in output in November. The reporting companies made about 84 per cent of the total output in 1918 and about 85 per cent in 1919. Ordinarily it may be assumed that the producers not reporting had approximately the same variations in output from month to month as the companies reporting, but in the case of November such an assumption is not correct, since the report doubtless includes all the Steel Corporation's output, the companies not reporting being among the independents. The corporation's output did not decrease materially from October to November, and probably increased somewhat. A computation taking this into account suggests that if the corporation's output was unchanged from October to November the output of the independents decreased by about 28 per cent, whereby the entire output decreased about 15 per cent. As independent production declined continuously the rate at present is much below the November average.

PIG IRON

Little change has occurred in pig iron prices in the past week. Prices on an average are approximately 20 per cent under the top level reached late last August and about 50 per cent above the Industrial Board schedule, which represented the market from the time of the Industrial Board adjustment, March 21, 1919, until October following. Declines thus far have been almost voluntarily on the part of furnaces, not being occasioned by competition for business, since scarcely any business has been offered. The remainder of the decline is likely to be left quite largely for more competitive times. Quotations for the valley market are: Foundry, \$37; bessemer, \$35; basic, \$33.

Lithium carbonate.....	lb. 1.15 - 1.16	1.15 - 1.16
Magnesium carbonate, technical.....	lb. 1.15 - 1.16	1.15 - 1.16
Magnesium sulphate, U. S. P.....	100 lb. 3.00 - 3.25	2.50 - 2.75
Magnesium sulphate, commercial.....	100 lb. 1.90 - 2.00	2.00 - 2.25
Methanol, 95%.....	gal. 1.15 - 1.16	1.15 - 1.16
Methanol, pure.....	gal. 1.15 - 1.16	1.15 - 1.16
Nickel salt, double.....	lb. 1.15 - 1.16	1.15 - 1.16
Nickel salt, single.....	lb. 1.15 - 1.16	1.15 - 1.16
Phosgene (see carbonyl chloride).....	lb. 1.15 - 1.16	1.15 - 1.16
Phosphorus, red.....	lb. 1.15 - 1.16	1.15 - 1.16
Phosphorus, yellow.....	lb. 1.15 - 1.16	1.15 - 1.16
Potassium bichromate.....	lb. 1.15 - 1.16	1.15 - 1.16

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar).....lb.		\$0.43 - \$0.47
Potassium bromide, granular.....lb.		.45 - .50
Potassium carbonate, U. S. P.....lb.	50 - .55	.56 - .60
Potassium carbonate, crude.....lb.	.13 - .13½	.13 - .14
Potassium chlorate, crystals.....lb.	.13 - .14	.15 - .18
Potassium hydroxide (caustic potash).....lb.	.16 - .16½	.16 - .17
Potassium iodide.....lb.		3.00 - 3.20
Potassium nitrate.....lb.	.14 - .16	.16½ - .17
Potassium permanganate.....lb.	.50 - .55	.56 - .60
Potassium prussiate, red.....lb.	.55 - .57	.58 - .60
Potassium prussiate, yellow.....lb.	.34 - .35	.35½ - .36
Potassium sulphate (powdered).....ton	\$240.00 - 255.00	
Rochelle salts (see sodium potas. tartrate)		
Sal ammoniac (see ammonium chloride)		
Salt soda (see sodium carbonate)		
Salt cake.....ton		45.00 - 50.00
Silver cyanide (nominal).....oz.		1.25 - 1.46
Silver nitrate (nominal).....oz.		.46 - .48
Soda ash, light.....100 lb.	1.90 - 2.00	2.10 - 2.30
Soda ash, dense.....100 lb.	2.50 - 2.75	3.00 - 3.25
Sodium acetate.....lb.	.08 - .08½	.08½ - .09
Sodium bicarbonate.....100 lb.	2.75 - 2.85	3.00 - 3.25
Sodium bichromate.....lb.	.09½ - .10	.10½ - .11
Sodium bisulphate (nitre cake).....ton	7.00 - 7.50	8.00 - 11.00
Sodium bisulphate powdered, U. S. P.....lb.	.06½ - .07	.07½ - .08
Sodium borate (borax).....lb.	.08 - .08½	.09 - .09½
Sodium carbonate (sal soda).....100 lb.	1.85 - 2.00	2.15 - 2.25
Sodium chlorate.....lb.	.10 - .10½	.11 - .11½
Sodium cyanide, 96-98 per cent.....lb.	.24 - .25	.26 - .28
Sodium fluoride.....lb.	.17 - .17½	.17 - .18½
Sodium hydroxide (caustic soda).....100 lb.	3.75 - 4.00	4.25 - 4.35
Sodium hyposulphite.....lb.		.04 - .04½
Sodium molybdate.....lb.	2.50 - 2.85	3.25 - 3.50
Sodium nitrate.....100 lb.		3.00 - 3.25
Sodium nitrite.....lb.	.07 - .07½	.08 - .08½
Sodium peroxide, powdered.....lb.	.35 - .40	.42 - .45
Sodium phosphate, dibasic.....lb.	.03½ - .04½	.04½ - .05
Sodium potassium tartrate (Rochelle salts) lb.		.33 - .35
Sodium prussiate, yellow.....lb.	.18 - .18½	.19 - .20
Sodium silicate, solution (40 deg.).....lb.	.01½ - .01½	.02 - .02½
Sodium silicate, solution (60 deg.).....lb.	.03 - .03½	.03½ - .04
Sodium sulphate, crystals (Glauber's salt) 100 lbs	1.75 - 2.00	2.15 - 2.25
Sodium sulphide, crystal, 60-62 percent (concl) lb.	.07 - .07½	.07½ - .08
Sodium sulphite, crystals.....lb.	.04 - .04½	.04½ - .05
Strontium nitrate, powdered.....lb.	.15 - .15½	.15 - .16
Sulphur chloride, red.....lb.	.08 - .09	.10 - .10½
Sulphur, crude.....ton	16.00 - 20.00	
Sulphur dioxide, liquid, cylinders.....lb.	.09 - .10	.10 - .12
Sulphur (sublimed), flour.....100 lb.		3.70 - 4.35
Sulphur, roll (brimstone).....100 lb.		3.40 - 3.90
Tin bichloride, 50 per cent.....lb.	.11 - .12	.12½ - .13
Tin oxide.....lb.		.50 - .51
Zinc carbonate, precipitate.....lb.	.16 - .18	.19 - .20
Zinc chloride, gran.....lb.	.12 - .13	.13½ - .14
Zinc cyanide.....lb.	.45 - .49	.50 - .60
Zinc dust.....lb.	.12 - .13	.13 - .14
Zinc oxide, XX.....lb.	.09½ - .09½	.10 - .10½
Zinc sulphate.....lb.	.03½ - .04	.04½ - .04½

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude.....lb.	\$1.10 - \$1.15
Alpha naphthol, refined.....lb.	1.45 - 1.50
Alpha naphthylamine.....lb.	.47 - .50
Aniline oil, drums extra.....lb.	.24 - .30
Aniline salts.....lb.	.30 - .32
Anthracene, 80% in drums (100 lb.).....lb.	.90 - 1.00
Benzaldehyde (f. f. c.).....lb.	2.00 - 2.10
Benzidine, base.....lb.	1.10 - 1.15
Benzidine sulphate.....lb.	1.05 - 1.10
Benzoic acid, U. S. P.....lb.	.75 - .80
Benzonitrile, U. S. P.....lb.	.75 - .85
Benzene, pure, water-white, in drums (160 gal.) gal.	.35 - .40
Benzene, 90%, in drums (100 gal.) gal.	.32 - .33
Benzyl chloride, 95-97%, refined.....lb.	.35 - .40
Benzyl chloride, tech.....lb.	.40 - .45
Beta-naphthol benzoate (nominal).....lb.	3.50 - 4.00
Beta-naphthol, sublimed (nominal).....lb.	.75 - .80
Beta-naphthol, tech (nominal).....lb.	.40 - .45
Beta-naphthylamine, sublimed.....lb.	2.25 - 2.40
Cresol, U. S. P., in drums (100 lb.).....lb.	.18 - .19
Ortho-cresol, in drums (100 lb.).....lb.	.23 - .25
Cresylic acid, 97-99%, straw color, in drums.....gal.	1.10 - 1.15
Cresylic acid, 95-97%, dark, in drums.....gal.	1.05 - 1.10
Cresylic acid, 50% first quality, drums.....gal.	.65 - .75
D chlorobenzene.....lb.	.07 - .10
Diethylaniline.....lb.	1.45 - 1.50
Dimethylaniline.....lb.	.70 - .80
Dinitrobenzene.....lb.	.30 - .37
Dinitrochlorobenzene.....lb.	.27 - .32
Dinitronaphthalene.....lb.	.42 - .45
Dinitrophenol.....lb.	.40 - .45
Dinitrotoluene.....lb.	.27 - .30
Dip oil, 25%, tar acids, car lots, in drums.....gal.	.38 - .40
Diphenylamine (nominal).....lb.	.75 - .77
H-acid (nominal).....lb.	1.60 - 1.65
Meta-phenylenediamine.....lb.	1.25 - 1.30
Monochlorobenzene.....lb.	.17 - .18
Monothylaniline.....lb.	1.75 - 2.25
Naphthalene crushed, in bbls. (250 lb.).....lb.	.09 - .09½
Naphthalene, flake.....lb.	.09 - .09½
Naphthalene, balls.....lb.	.10 - .10½
Naphthalonic acid, crude.....lb.	.70 - .75
Nitrobenzene.....lb.	.12 - .15
Nitronaphthalene.....lb.	.40 - .50
Nitro-toluene.....lb.	.18 - .25
Ortho-amidophenol.....lb.	3.20 - 3.75
Ortho-dichlorobenzene.....lb.	.15 - .20
Ortho-nitro-phenol.....lb.	.75 - .80
Ortho-nitro-toluene.....lb.	.25 - .40
Ortho-toluidine.....lb.	.30 - .32
Para-amidophenol, base.....lb.	2.20 - 2.25
Para-amidophenol, HCl.....lb.	2.10 - 2.15
Para-dichlorobenzene.....lb.	.10 - .15
Paranitroaniline.....lb.	1.05 - 1.10

Para-nitrotoluene.....lb.	1.25 - 1.40
Para-phenylenediamine.....lb.	2.20 - 2.35
Para-toluidine.....lb.	1.35 - 2.00
Phthalic anhydride.....lb.	.60 - .70
Phenol, U. S. P., drums (dest.), (240 lb.).....lb.	.08 - .10
Pyridine.....gal.	2.00 - 3.50
Resorcinol, technical.....lb.	2.75 - 3.00
Resorcinol, pure.....lb.	3.75 - 4.00
Salicylic acid, tech., in bbls. (110 lb.).....lb.	.33 - .35
Salicylic acid, U. S. P.....lb.	.37 - .40
Salol.....lb.	.85 - .95
Solvent naphtha, water-white, in drums, 100 gal. gal.	.30 - .35
Solvent naphtha, crude, heavy, in drums, 100 gal. gal.	.19 - .22
Sulphanilic acid, crude.....lb.	.32 - .35
Toluidine.....lb.	1.40 - 1.45
Toluidine, mixed.....lb.	.45 - .55
Toluene, in tank cars.....gal.	.35 - .40
Toluene, in drums.....gal.	.38 - .40
Xylidines, drums, 100 gal.....lb.	.45 - .50
Xylene, pure, in drums.....gal.	.45 - .50
Xylene, pure, in tank cars.....gal.	.40 - .42
Xylene, commercial, in drums, 100 gal.....gal.	.37 - .38
Xylene, commercial, in tank cars.....gal.	.30 - .35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....lb.	\$0.26 - \$0.27
Beeswax, refined, light.....lb.	.28 - .35
Beeswax, white pure.....lb.	.35 - .40
Carnauba, No. 1, (nominal).....lb.	.80 - .90
Carnauba, No. 2, North Country.....lb.	.37 - .38
Carnauba, No. 3, North Country.....lb.	.25 - .26
Japan.....lb.	.19 - .20
Montan, crude.....lb.	.12 - .14
Paraffine waxes, crude match wax (white) 105-110 m.p.....lb.	.07 - .08
Paraffine waxes, crude, scale 124-126 m.p.....lb.	.07 - .07½
Paraffine waxes, refined, 118-120 m.p.....lb.	.09 - .09½
Paraffine waxes, refined, 125 m.p.....lb.	.09½ - .09½
Paraffine waxes, refined, 128-130 m.p.....lb.	.10 - .11
Paraffine waxes, refined, 133-135 m.p.....lb.	.13 - .14
Paraffine waxes, refined, 135-137 m.p.....lb.	.14 - .15
Stearic acid, single pressed.....lb.	.15 - .16
Stearic acid, double pressed.....lb.	.16 - .16½
Stearic acid, triple pressed.....lb.	.16 - .17½

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr. 0.930-0.940.....gal.	\$1.75
Pine oil, pure, dist. dist.....gal.	1.65
Pine tar oil, ref., sp. gr. 1.025-1.035.....gal.	.48
Pine tar oil, crude, sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla., gal.	.35
Pine tar oil, double ref., sp. gr. 0.965-0.990.....gal.	.65
Pine tar, ref., thin, sp. gr. 1.080-1.060.....gal.	.34
Turpentine, crude, sp. gr. 0.900-0.970.....gal.	.70
Hardwood oil, f.o.b. Mich., sp. gr. 0.960-0.990.....gal.	.35
Pine wood creosote, ref.....gal.	.55

Naval Stores

The following prices are f.o.b. New York, for carload lots

Resin B-D, bbl.....280 lb.	\$10.00 -
Resin E-I.....280 lb.	10.00 -
Resin K-N.....280 lb.	10.00 -
Resin W. (G. W. W.).....280 lb.	10.25 -
Wood rosin, bbl.....280 lb.	11.10 -
Spirits of turpentine.....gal.	.80 -
Wood turpentine, steam dist.....gal.	.79 -
Wood turpentine, dist. dist.....gal.	.79 -
Pine tar pitch, bbl.....200 lb.	8.50 -
Tar, kiln burned, bbl. (500 lb.).....bbl.	15.00 -
Retort tar, bbl.....500 lb.	15.00 - 15.50
Rosin oak, first run.....gal.	.70 -
Rosin oil, second run.....gal.	.73 -
Rosin oil, third run.....gal.	.90 -

Solvents

73-76 deg., steel bbls. (85 lb.).....gal.	\$0.41
70-72 deg., steel bbls. (85 lb.).....gal.	.39
68-70 deg., steel bbls. (85 lb.).....gal.	.38
V. M. and 4° naphtha, steel bbls. (85 lb.).....gal.	.30

Crude Rubber

Para—Upriver fine (nominal).....lb.	\$0.22 - \$0.23
Upriver coarse (nominal).....lb.	.14 - .15
Upriver cauchou ball (nominal).....lb.	.16 - .16½
Plantation—First latex crepe.....lb.	.19 -
Ribbed smoked sheets.....lb.	.18 -
Brown crepe, thin, clean.....lb.	.16 -
Amber crepe No. 1.....lb.	.17 -

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls.....lb.	\$0.13 - \$0.14
Castor oil, AA, in bbls.....lb.	.15 - .15½
China wood oil, in bbls. (f.o.b. Pac. coast).....lb.	.11 - .11½
Cocanut oil, Ceylon grade, in bbls.....lb.	.13 - .14
Cocanut oil, Ceylon grade, in bbls (nominal).....lb.	.15 - .16
Cora oil, crude, in bbls.....lb.	.09½ - .10
Cottonseed oil, crude (f.o.b. mill).....lb.	.06 - .07
Cottonseed oil, summer yellow.....lb.	.09½ - .10
Cottonseed oil, winter yellow.....lb.	.11 - .12
Linseed oil, raw, car lots (domestic).....gal.	.80 -
Linseed oil, raw, tank cars (domestic).....gal.	.75 - .77
Linseed oil, boiled, car lots (domestic).....gal.	.82 -

Olive oil, commercial.....	gal	2.75	3 00
Palm, Lagos.....	lb.	.08	.09
Palm, Niger.....	lb.	.07	.08
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.08	.09
Peanut oil, refined, in bbls.....	lb.	.14	.14
Rapeseed oil, refined in bbls.....	gal.	1.15	1 20
Rapeseed oil, blown, in bbls.....	gal.	1.25	1 35
Soya bean oil (Manchurian), in bbls, N. Y.....	gal.	.09	1 10
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.06	07

FISH

Light pressed Menhaden.....	gal.	\$0.65	\$0.70
Yellow bleached Menhaden.....	gal.	.67	.70
White bleached Menhaden.....	gal.	.72	.75
Blown Menhaden.....	gal.	1.05	1.10

Miscellaneous Materials

All f. o. b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$24.00	\$30.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	22.00	26.00
Barytes, crude, 88% (a. 94% ba. Kings Creek.....	net ton	10.00	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	28.00
Barytes, crude, first grade, Missouri.....	net ton	10.00	12.00
Blanc fixe, dry.....	lb.	.05	.05
Blanc fixe, pulp.....	net ton	60.00	65.00
Caseine.....	lb.	.14	.18
Chalk, domestic, extra light.....	lb.	.05	.06
Chalk, domestic, light.....	lb.	.04	.05
Chalk, domestic, heavy.....	lb.	.04	.05
Chalk, English, extra light.....	lb.	.05	.07
Chalk, English, light.....	lb.	.05	.06
Chalk, English, dense.....	lb.	.04	.05
China clay (Kaolin) crude, f.o.b. mines, Georgia	net ton	8.00	10.00
China clay (Kaolin) washed, f.o.b. Georgia.....	net ton	12.00	15.00
China clay (Kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	22.00
China clay (Kaolin) crude f.o.b. Virginia points	net ton	8.00	12.00
China clay (Kaolin) ground, f.o.b. Virginia points	net ton	15.00	40.00
China clay (Kaolin), imported, lump.....	net ton	25.00	35.00
China clay (Kaolin), imported, powdered.....	net ton	30.00	35.00
Feldspar, crude, f.o.b. Maryland and North Carolina points	gross ton	8.00	14.00
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	30.00
Fuller's Earth, f.o.b. New York.....	net ton	16.00	17.00
Fuller's earth, granular, f.o.b. Fla.....	net ton	25.00	—
Fuller's earth, powdered, f.o.b. Fla.....	net ton	18.00	—
Fuller's earth, imported, powdered.....	net ton	35.00	40.00
Graphite, crucible, 90% carbon, Ashland, Ala.	lb.	.11	.09
Graphite, crucible, 85% carbon, Ashland, Ala.	lb.	.07	.09
Graphite, higher lubricating grades.....	lb.	.04	.40
Pumice stone, imported, lump.....	lb.	.06	.50
Pumice stone, domestic, lump.....	lb.	.04	.07
Pumice stone, ground.....	lb.	.04	.07
Quartz (acid tower) 1st to 4th, f.o.b. Baltimore	net ton	—	10.00
Quartz (acid tower) 1st to 4th, f.o.b. Baltimore	net ton	—	14.00
Quartz (acid tower) 1st to 4th, f.o.b. Baltimore	net ton	—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	7.50
Shellac, orange fine.....	lb.	1.00	1.05
Shellac, orange superfine.....	lb.	1.05	1.10
Shellac, A. C. garnet.....	lb.	.90	.95
Shellac, T. N.....	lb.	.85	.95
Sonapstone.....	ton	15.00	25.00
Sodium Chloride.....	long ton	—	17.50
Talc, paper-making grades, f.o.b. Vermont.....	ton	12.00	22.00
Talc, roofing grades, f.o.b. Vermont.....	ton	9.50	15.00
Talc, rubber grades, f.o.b. Vermont.....	ton	12.00	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	12.00	15.00
Talc, imported.....	ton	60.00	70.00
Talc, California Talcum Powder grade.....	ton	20.00	45.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh	1,000	160
Chrome brick, f.o.b. Eastern shipping points	net ton	100 110
Chrome cement, 40-45% Cr ₂ O ₃	net ton	55-60
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points	net ton	60-65
Fire clay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	55-60
Fire clay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works	1,000	45-50
Magnesite brick, 9-in. straight	net ton	121
Magnesite brick, 9-in. arches, wedges and keys	net ton	134
Magnesite brick, soaps and spalls	net ton	134
Silica brick, 9-in. sizes, f.o.b. Chicago district	1,000	65-70
Silica brick, 9-in. sizes, f.o.b. Birmingham district	1,000	56-61
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.	1,000	55-60

Ferro-Alloys

All f.o.b. Works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	\$200.00	\$225.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon, carlots.....	lb.	.17	.18
Ferro-chrome, per lb. of Cr. contained, 4-6% carbon, carlots.....	lb.	.16	.17
Ferro-manganese, 76-80% Mn, domestic.....	gross ton	140.00	145.00
Ferro-manganese, 76-80% Mn, English.....	gross ton	135.00	140.00
Spiegel, 18-22% Mn.....	gross ton	60.00	65.00
Ferro-molybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.00	2.50
Ferro-silicon, 10-15%.....	gross ton	60.00	65.00
Ferro-silicon, 50%.....	gross ton	80.00	85.00
Ferro-silicon, 75%.....	gross ton	—	160.00
Ferro-tungsten, 70-80% per lb. of contained W.....	lb.	.65	.75
Ferro-uranium, 35-50% of U, per lb. of U content.....	lb.	7.00	—
Ferro-vanadium, 30-40% per lb. of contained V.....	lb.	6.50	7.50

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al content, less than 2% moisture, up to 20% silica, not more than 114% moisture.....	gross ton	\$10.00	\$11.00
Chrome ore, Calif. concentrates, 50% min.....	unit	.60	.65
Chrome ore, 50%, Cr ₂ O ₃ , f.o.b. Atlantic Seaboard.....	unit	.60	.65
Coke, foundry, f.o.b. ovens.....	net ton	9.00	10.50
Coke, furnace, f.o.b. ovens.....	net ton	8.00	9.00
Coke, petroleum, refinery, Atlantic Seaboard.....	net ton	24.00	26.00
Fluor spar, lump, f.o.b. Tonuco, New Mexico.....	net ton	17.00	—
Fluor spar, standard, domestic washed gravel Kentucky and Illinois mines.....	net ton	22.50	25.00
Ilmenite, 52% TiO ₂ , per lb. ore.....	lb.	.01	.01
Manganese Ore, 50% Mn, c.i.f. Atlantic seaport.....	unit	45	50
Manganese ore, chemical (MnO ₂).....	gross ton	65.00	70.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂ , N. Y. lb.	lb.	.55	.60

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Colorado

AULT—The Great Valley Sugar Co., Central Savings Bank Bldg., Denver, has awarded the contract for the construction of a sugar factory to the Schwarz Eng. Co., Mack Bldg., Denver. Estimated cost, \$1,000,000.

LAFAYETTE—The Great Valley Sugar Co., Central Savings Bank Bldg., Denver, has awarded the contract for the construction of a sugar factory to the Schwarz Eng. Co., Mack Bldg., Denver. Estimated cost, \$1,000,000.

PLEASANT VALLEY (Nock P. O.)—The Great Valley Sugar Co., Central Savings Bank Bldg., Denver, has awarded the contract for the construction of a sugar factory to the Schwarz Eng. Co., Mack Bldg., Denver.

Idaho

WEISER—The city plans an election Jan. 4 to vote on \$150,000 bonds to improve water-works, including a filtration plant. Burns & McDonnell, 102 Interstate Bldg., Kansas City, Mo., consulting engineers.

Illinois

CENTRALIA—The American Rubber Co., 1526 South Wabash St., will soon award the contract for the construction of a 2-story, 60x100-ft. rubber factory. Estimated cost, \$100,000. The Consulting Co., 2801 Union Central Bldg., Cincinnati, archit.

SPRINGFIELD—The city is having plans prepared for the construction of an iron removal and softening plant to have a 15,000,000-gal. capacity. Burns & McDonnell, 102 Interstate Bldg., Kansas City, Mo., consult. engs.

Indiana

KENDALLVILLE—The Noble Tire & Rubber Co. will receive bids after Jan. 1 for the construction of a 2-story, 50x200-ft. rubber factory. Estimated cost, \$75,000. A. M. Strauss, 707 Bank Bldg., Ft. Wayne, archit.

TERRE HAUTE—The Union Hospital, 7th and 8th Aves., plans to build a 6-story, 11x200 ft. hospital. Laboratory equipment will be installed in same. Estimated cost, \$300,000. Johnson, Miller & Miller, 105 South 7th St., archts.

Iowa

DES MOINES—The Salvation Army, S. E. 6th St. and Indiana Rd., has had plans prepared for the construction of a 2-story, 51x136 ft. maternity hospital. A chemical laboratory will be installed in same. Estimated cost, \$100,000. Sawyer & Watrous, 101 Hippie Bldg., archts.

POCAHONTAS—The Bd. Educ. will receive bids for the construction of a 2-story, 56x110-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$150,000. W. E. Hulse & Co., 309 Securities Bldg., Des Moines, archit.

TRIPOLI—The Bd. Educ. will receive bids about Feb. 15 for the construction of a 3-story, 61x100 ft. grade and high school. A chemical laboratory will be installed in same. Estimated cost, \$200,000. Keffer & Jones, 204 Masonic Temple, Des Moines, Iowa, archts.

WILLIAMS—The Currie Eng. Co., Webster City, has awarded the contract for the construction of a sewage disposal plant, to W. E. Welden, Iowa Falls. Estimated cost, \$1,369.

Kansas

BAXTER SPRINGS—The General Amer. Oil Co., 601 New First Natl. Bank Bldg., Tulsa, Okla., will build a 1-story oil refinery in the southern-eastern section of the town. Estimated cost, \$100,000.

Minnesota

WAYZATA—The Bd. Educ. has awarded the contract for the construction of a 1-story, 200x200-ft. grade and high school, to the Madsen Constr. Co., 818 Builders

Exch. Bldg., Minneapolis. A chemical laboratory will be installed in same. Estimated cost, \$131,915.

New Jersey

CAMDEN—J. B. Van Selver Co., Market St. Ferry, has awarded the contract for the construction of a 1-story, 30x70-ft. kiln building, to P. Haibach, 26th and Thompson Sts., Philadelphia, Pa.

NEW BRUNSWICK—The State of New Jersey is having plans prepared for the construction of a 2-story, 50x80-ft. ceramic building. Estimated cost, \$100,000. P. H. Bent, 112 West State St., Trenton, archit.

RIDGEFIELD—The Continental Paper Box Co., 122 Washington St., Brooklyn, N. Y., will soon award the contract for the construction of a 2-story, 100x500 ft. factory on Grand and Hall Sts. Estimated cost, \$250,000. W. E. Wells, Inc., 1181 Myrtle Ave., Brooklyn Ave., Brooklyn, N. Y., archit. and engr.

North Dakota

UNDERWOOD—The Bd. Educ. will soon receive bids for the construction of a 2-story high school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. W. D. Gillespie, 615 Bway, Fargo, archit.

Ohio

CLEVELAND—The Crossley Rubber Co., 2170 East 18th St., has awarded the contract for the construction of a 1-story, 30x10-ft. factory, to G. E. Peterson, 1921 Euclid Ave. Estimated cost, \$10,000.

CLEVELAND—The Premier Refining Co., 1187 West 11th St., plans to alter the 2-story factory on Howard Ave. Estimated cost, \$35,000. Service Constr. Co., 6110 Euclid Ave., archit.

COLUMBUS—Ohio State University plans to construct an experimental laboratory building. Estimated cost, \$50,000. J. N. Bradford, archit.

Texas

DALLAS—The Bd. Educ., Municipal Bldg., has awarded the contract for the construction of a 2-story high school on Haskell and McKinney Sts., to the Amer. Constr. Co., 111 Gulf Bldg., Houston. A chemical laboratory and equipment will be installed in same. Estimated cost, \$765,000.

West Virginia

CHARLESTON—The city plans to build an electric chlorine plant and install meters in same.

Wisconsin

JANESVILLE—The Bd. Educ. is having plans prepared for the superstructure of a 3-story, 180x200-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$500,000. VanDyke & DeGidike, Caswell Bldg., Milwaukee, archts.

NEENAH—The Neenah Paper Co. has awarded the contract for the construction of a 1-story, 60x130-ft. water filter plant, to C. R. Meyer & Sons Co., 50 State St., Oshkosh. Filters will be installed in same.

TWO RIVERS—The Bd. Educ. will receive bids about Jan. 1 for the construction of a 3-story, 96x110-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$100,000. J. D. Chubb, 109 North Dearborn St., Chicago, Ill., archit.

British Columbia

PRINCE GEORGE—The Eastern Syndicate will receive bids in January for the construction of a pulp and paper plant, etc. Estimated cost, \$6,000,000.

VANCOUVER—The Coast Range Steel Co., 119 Metropolitan Bldg., recently incorporated with \$15,000,000 capital stock, plans to build a large iron and steel works near here.

Ontario

WALLACEBURG—The Wallaceburg Glass Co., Ltd., plans to expend \$50,000 on its plant. Equipment will be installed in same.

WELLAND—The Cross Mfg. Co., Sydney, N. S., plans to build a fertilizer plant here. Estimated cost, \$250,000.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29, 1921.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting Feb. 14 to 17 in New York City.

AMERICAN PHYSICAL SOCIETY will hold its annual meeting, beginning Dec. 28, at Chicago, it being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

COMMON BRICK MANUFACTURERS' ASSOCIATION OF AMERICA will hold its annual meeting at the Hotel Pennsylvania, New York City, Jan. 31 to Feb. 4.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at the Statler Restaurant, Newark, N. J., the second Monday of every month.

SOCIETY OF CHEMICAL INDUSTRY holds its Perkin Medal Award Meeting at Rumford Hall, Chemists' Club, New York, on Jan. 11, 1921.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Jan. 7, American Chemical Society; Jan. 11, Society of Chemical Industry, Perkin Medal award; Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society, Nichols Medal award; March 25, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Industrial Notes

W. S. QUIGLEY, president Quigley Furnace Specialties Co., New York City, has just returned from Europe after an extensive trip made in connection with large installations of the Quigley Powdered Coal System in Italy and Belgium.

THE MISSOURI PORTLAND CEMENT CO. has established offices at the Union and Planters Bank Bldg., Memphis, Tenn. The company is installing a large sand and gravel producing plant in that city to operate in conjunction with the present plant in South Memphis.

THE ALUMITE LUBRICATOR CO. of Chicago, Ill. has established district offices at 47 Monroe Ave., Memphis, Tenn. George Hyatt is local manager of the new office.

THE GENERAL MANUFACTURING CO., with a capital of \$150,000, has been established at 390 South Front St., Memphis, Tenn., and will manufacture insecticides and perfumes.

THE MEMPHIS SILICA CO. has acquired a 20-acre silica deposit at Riverton Junction, Ala., and is now arranging for truckage to serve the mines. The executive sales headquarters of the company will be located in Memphis and the product will be distributed for use in manufacture of paint, glass, pottery, cement, cleansers, etc., N. E. Goddard is president, W. J. Whitford vice-president, and J. B. Druschel secretary-treasurer of the new company.

THE NORTHERN REFRACTORIES CO. has been organized with main offices at Ridge-way, Pa., Ives L. Harvey, president, M. T. Shanley, secretary. It is opening up deposits of high-grade clay on its property at Hutchins, Pa., and will put on the market a high-grade flint and ground clay.

THE AMERICAN DRESSLER TUNNEL KILNS, INC., has moved its executive, engineering and thermal offices to 1740 East Twelfth St., Cleveland, O.

ENGLE TILE & FUEL CO. of Newton, Ia., will install a direct heat-radiating drier. This plant specializes on drain tile.

Chemical Engineers Visit the South

NEW ORLEANS and Louisiana played host to the American Institute of Chemical Engineers Dec. 6 to 9 and carried off their part delightfully, sustaining their reputation for unbounded hospitality and courtesy to the stranger within their gates. There are but four men in Louisiana who boast membership in the Institute, and while it was to their efforts primarily that the success of the meeting was due, they were loyally supported by city and state authorities, local chambers of commerce in the different towns visited, and railroad authorities who co-operated in making the Institute's path comfortable. On the whole it is doubtful if the Institute has had a more agreeable and successful winter meeting. Louisiana's three S's, salt, sulphur and sugar, were objects of more than ordinary interest. Methods of producing the first two are unique in the recovery of those minerals from beneath the earth's surface, while in the case of the second we have an example of the daring ingenuity and vision of a chemical engineer who succeeded in exploiting the deposit after two failures had been made.

The Institute does well to plan its semi-annual meetings in such a way that acquaintance and sociability are promoted simultaneously with the dissemination of technical knowledge and a study of natural resources and chemical industries. A week or ten days of travel, more than any other feature of a technical meeting, is conducive to the making of acquaintances and friends. It relieves the monotony of sessions for the reading and discussion of technical papers and affords the best opportunity for education through observation and contact. From all these points of view the recent meeting in Louisiana was a marked success.

Enter the Physicist Into Industrial Research

A PROMINENT chemical company has recently appointed a physicist as a member of its research organization. Numerous other large industrial concerns are recognizing this variety of scientist with increasing frequency of late. The reason for this industrial appreciation of workers in our related science is not hard to determine. There is in the present tendency not only encouragement for physicists but also a note of warning for chemists.

A well-planned collegiate course of chemical instruction includes physical chemistry and numerous of its important variations, such as thermal chemistry, electrochemistry, photochemistry, etc. However, very often the student completing even the well-balanced curriculum has passed over much too lightly the fundamentals of physics. Frequently it is quite true, as jockingly remarked, that "the chemist is a man who makes bad physical measurements on pure substances;

whereas the physicist makes wonderful physical measurements of the properties of impure materials." This situation was an early contributing reason for the development of a border field known as physical chemistry. However, even a thorough cultivation of this field is not enough, for fundamental physics must be studied and used by every well-trained chemist.

There will continue to be an increasing number of physicists employed by industry and all chemists can rejoice in this recognition of related science, but for many years to come a vast majority of our research organizations will probably not afford this "high-church form of scientist." It behooves the chemist, therefore, in building his research organization to make sure that some at least of his investigators are capable of caring for the purely physical problems with which any group of investigators is inevitably confronted. This, like many other factors, is simply one of the important things to take into account in planning a research organization. And incidentally, one may add, research organizations will succeed only when well planned; they are not much good if allowed to become a *Topsy*, who "just grewed."

Obstacles to Dye Legislation

DESPITE the serious situation facing the domestic dye industry and the fact that an overwhelming majority in each house of Congress is ready to vote for the dye bill in substantially its present form, it is becoming increasingly apparent that a small minority has an excellent chance of preventing the passage of the measure at this session of Congress. Representatives of the dye industry now in Washington declare that failure to obtain this legislation will drive to the wall all but the very largest concerns engaged in the manufacture of dyes.

Senator MOSES of New Hampshire is regarded as the chief obstacle in the path of this legislation. He is credited with reflecting the views of certain manufacturers of textiles, but it is known that fully 50 per cent of the textile manufacturers favor the passage of legislation which will insure the continuity of the domestic dye industry. Nevertheless Senator MOSES is understood to be ready to direct a filibuster against the measure.

The chief claim of the opposition is that the bill plays into the hands of two large corporations engaged in the manufacture of dyes. Apparently no note is being taken of the signed statements submitted by sixty-four small manufacturers, stating that the bill is more in the interest of the small than of the large manufacturer.

At the short session of Congress the amount of legislation which can be handled, in addition to the appropriation bills, is limited. The appropriation bills have right of way. With a large number of other bills of

great importance before Congress there is much opposition to the consideration of any measure which is likely to develop a filibuster, thus consuming a great deal of the precious time not occupied by the appropriation bills.

The program is to pass a peace resolution as one of the first acts in the extra session. This will automatically abolish the War Trade Section of the State Department and will remove the control which that organization has been exercising over imports of dyes. The War Trade Section has been limiting imports to dyes not made in this country or to those not made in sufficient quantity. Germany anticipates the lapsing of the license system prior to the enactment of an embargo measure and already is prepared to take full advantage of the situation by moving in a short interval large stores of dyes into this country. Friends of the dye industry and advocates of industrial independence for this country should use all legitimate means to secure legal legislation which will enable us to hold the advantages already gained.

Significance of Price Declines

IT IS a very important fact that Bradstreet's index number stood at 13.6263 on the first day of this month. The index number is a weighted average of commodity prices at wholesale. It is regarded by business men as properly planned and correctly carried out, so that it is really indicative of what it purports to represent.

To make the number 13.6263 more interesting it may be mentioned that the number at the beginning of last February was 20.8690, while the average in the ten years 1904 to 1913 was 8.59637. The number of Feb. 1 marked the high point. It was 142.8 per cent above the ten-year pre-war average, while the number on the first of this month was only 58.5 per cent above. From Feb. 1 to Dec. 1 there was a decline of 34.7 per cent.

This subject of prices is of universal interest. Everyone has to spend money for commodities and is thus directly interested, while many have to purchase services and there is some relation between prices of services and prices of commodities. Those who sell goods are necessarily interested in the general average of prices.

Of the general public the number of men who will endeavor to explain away Bradstreet's index number of Dec. 1 is exceeded only by the number who will pay no attention to it, yet it is an important fact and an illuminating one when properly studied. To explain it away some men will drop into the latest vernacular and say, "But it don't mean anything," because the average man doesn't buy "hides and leather" or "textiles" or "naval stores," which have shown particularly great declines in the past ten months. The real point is that the index number is of wholesale prices and the declines have not all worked out in retail prices. That means simply that they will. Other men will say that some of the low prices of Dec. 1 are due to the existence of unwieldy stocks, that goods are being sold at "a loss" or at "less than cost of duplication," as if the cost of duplication could be known when production costs are declining.

At one time we had the "ascending spiral" and now we have the descending spiral. One decline will bring on another. Declines in prices at wholesale have not fully worked out in declines at retail, whereas the latter should be the greater, as unusual profits had been

added. With reduced cost of living, wages can be reduced and manufacturing costs will decline.

There has been much talk and little study of "pre-war prices." Plot them, or even look at them, using Bradstreet's as a criterion. There is no pre-war "level" at all, but a sinuous line trending upward from 1896 as a low point in all the time since 1892. There were fluctuations before the war, why not after the war? It was as foolish to assert that prices were going to stay at a certain level as to pretend that they ever had stayed at any other level. There was, in fact, a fairly steady rise from 1896 to 1913. There were short "off" periods, of which 1908-9 and 1911 were good samples. While the ten-year average 1904 to 1913 inclusive was 8.59637, the highest yearly average was for 1913, 9.2115. Naturally we are thinking of 1921. That is eight years ahead of 1913, and going eight years back of 1913 we find 1905, a normal year in its time, with an average of 8.0988. Carrying the progression forward, by adding to 1913 the difference between 1905 and 1913 we have 9.2115. To get to that level would come nearer getting to "normal" than getting back to any of the numbers actually recorded before the war, but to get to 9.2115 from the present 13.6263 would be going down only 32 per cent. After all, then, there is not much to quarrel about.

Locking the Barn Too Late

THE horse was stolen recently, and although perhaps in general circles there was not as much commotion as if Man o' War had been led away by thieves, yet in the ceramic industry there has been almost equal disturbance. We refer to the case of the resignation of A. V. BLEININGER from his position as ceramic engineer of the staff of the Bureau of Standards to go into commercial work. This resignation had barely been announced when the most vigorous protests from many sources reached the bureau. It is evident that the ceramic industry as a whole had thoroughly appreciated the value to it of the service which had been rendered by Dr. BLEININGER's organization, and it is also evident that the industry is now much disturbed that he will no longer be available to serve it thus.

Running all through these protests to the bureau is the thought that Dr. BLEININGER could not have been expected to stay under the conditions of inadequate salary both for himself and for his staff. For a long time it has been well known that his work was most disheartening because of the frequent resignations of his more valuable assistants, usually just as they were getting thoroughly acquainted with the work and becoming increasingly valuable to the bureau in its investigations. And yet nothing, or virtually nothing, had been done about it until after conditions got so bad that Dr. BLEININGER found it necessary to resign.

There is a little consolation in the fact that Dr. BLEININGER has left nominally for a single year and that the bureau hopes to have him resume his work in direction of the ceramic investigations at the end of this period. However confident the industry may feel that it will be possible for him to take up the work again at that time, it cannot look with equanimity upon a whole year of delay in this important field.

This is only one of the many cases where valuable scientific investigators much needed in their present official position by the industries are in danger of extreme discouragement leading to separation from the

service. Other industries which find Government activity as valuable and as diplomatically handled as that which has been directed by Dr. BLEININGER may find it wise to investigate the situation in Washington and see if they too are not in danger of losing that service upon which they perhaps now depend more than they realize. An insistence upon retention of work of this sort upon a high plane with properly compensated chiefs and assistants not only will insure continuance of the work but also will safeguard against the dangers of petty administration and unsympathetic or actually antagonistic governmental attitude toward industrial technology. It would be well if more industries bought a new lock to secure their barn door.

Absurd Chemical Consolidation Ideas

RECENTLY one of the members of Congress made what was to him an amazing discovery that thirty-five different Government bureaus or commissions were doing chemical work or employed chemists. As a result this worthy legislator would revise our Government organization post haste, consolidate all chemical activities in one bureau, and thereby, to his mind, eliminate duplication, increase efficiency and reduce greatly the necessary Government expenditures for this scientific service.

The worthy legislator was probably conservative in stating that at least thirty-five different Government organizations do chemical work. In fact, in making this estimate he probably overlooked a number of them. But he certainly overlooked another factor in the matter much more pertinent than those which have occurred to him. Chemistry is in many instances the servant of industry, and in the Government department it is correspondingly the servant. The Geological Survey employs chemists; so, also, does the Bureau of Mines, the Bureau of Standards and the Bureau of Chemistry. However, no one who knows anything of the work of these four typical institutions would expect the Survey chemists, who are experts in mineral analysis, to care successfully for the food and drug problems of the Bureau of Chemistry, or the paint investigations at the Bureau of Standards, or the gasoline studies of the Bureau of Mines. The chemist has become better known industrially and in the halls of our legislatures during recent years than almost any other kind of scientist, but the education of the public and our Congressmen is still far from complete. No opportunity can be lost to make it clear that the term "chemist" is a generic word including many classes and varieties of workers. All of them have a common interest and use somewhat similar methods. But each in his sphere is a specialist, invaluable there, perhaps, but probably of relatively less value in any other field.

Chemists themselves are sometimes prone to forget these facts. They seem willing to rush into any variety of chemistry whether they are experienced or capable therein or not. It is not strange, therefore, that our legislators are disposed to take such stand as that recently exhibited. If the leaders of the profession have influence, however, there is no reason to believe that serious legislation such as that which has been suggested will materialize. We certainly hope it will not, for one might as well say that all typewriting machines must be maintained and used in a single building as to think that all chemists in the Government service could work to advantage through a single bureau.

Chemists And Cooks

A COUPLE of members of the Chemists' Club were walking along 41st St., New York, and as they approached the entrance of the club, whither they were bound for their lunch, an automobile drew up to the back door of the hotel across the way. The chauffeur stepped down and politely provided an exit for his passenger. "Let's wait a minute," said the older chemist to his colleague. "That is probably the chef of the hotel, arriving for his day's work." Sure enough it was. A well-dressed man with a foreign air touched an electric button, an elevator appeared beyond a door, and the chief cook entered it and disappeared into the depths. It was as it should be. Cooking is a great art, and the hotel is successful. A large measure of its success depends upon its chef, who is, very properly, a man of circumstance. He is entitled to the luxuries and ease which often accompany achievement.

On the other hand, the two chemists walked, which was also good for them, for the exercise was conducive to their health. But in a moment of confidence they admitted to each other as they proceeded to the club dining-room for their 95-cent lunches that neither possessed an automobile. That, too, may also be as it should, because likely as not neither of them needs one. One of them also observed that as things are going now a far more important desideratum than an automobile for a chemist is a job, although the two who were engaged in the observation and comment were not lacking in this respect.

Why should not cooking be a profession anyway? The consulting chemist is always ready to work over a face powder or a toilet soap, and he likes the opportunity, whereas if he is asked to cook a dinner the chances are that he will decline with the semblance of scorn. Now a leading reason for his refusal and scorn is likely to be that he can't do it; that he doesn't know how. He lacks what the bewhiskered foreigner in the luxurious automobile has in abundance, and that is The Art.

Our food chemists measure calories and allocate proteins, hydrocarbons and fats, and provide for the economies of householding, but why shouldn't they provide for the joy of living as well? If a poet writes a ballad that finds its way into popularity and everybody sings it he counts it to his credit. Dishes of appetizing food, on the other hand, seldom bear the names of their creators; they are more frequently named for eminent French statesmen, or for celebrated gourmets. We should like to see the names of our great chemists more frequently rolled off the public tongue. Advertising men charge millions of dollars and grow rich by inducing the public to become familiar with names of purveyors and of the goods they sell. This sort of thing has its value. And it would be good for chemistry. Think of a menu containing such items as Oysters, Ghent, à la Baekeland; Potage Vitamines à la Mendel; Scrod à la Theodore W. Richards; Prairie Hen à la W. A. Noyes; Salade Mathématique, Langmuir, prepared with Huile Baskerville and Vinaigre Whitaker; Gâteaux à sucres divers, Hudson.

All of these gentlemen have the mind and the ability to do these things; as for Dr. BAEKELAND, we speak from experience when we say that in the galley of a boat he can produce dishes of supreme merit and that if his preparations were on the market the hotels would bid all sorts of prices for them.

Readers' Views and Comments

Joaquim Bishop, Worker in Platinum

To the Editor of Chemical & Metallurgical Engineering

SIR: I have noticed that Dr. Smith has very little to say, in his books upon the early history of chemistry in America, about the work of Joaquim Bishop, who was assistant to Robert Hare. Bishop became very familiar with Hare's oxyhydrogen blowpipe and used it in working platinum. In 1873, when I was in the private chemical laboratory of Dr. Thomas M. Drown at 1223 Girard St., Philadelphia, Bishop, then by no means a young man, dressed in the straw hat and cowhide boots of a farmer, with a market basket on his arm containing his week's product of platinum crucibles, came to the city from Sugartown to dispose of his product to Bullock & Crenshaw, whose store was located at Sixth and Arch. He frequently came to our laboratory, in response to a request from Dr. Drown, to get instructions about the manufacture of apparatus of platinum. At that time pieces made of platinum were soldered together with gold. Shortly afterward he reported that he could weld them; gold could be dispensed with. He made some rather intricate pieces for us, without any boasting about his skill, which was very great. He was very plain in manner and speech, rather tall, with a pleasant smile. About 1882 I went up to Catasauqua to see H. J. Seaman, then chemist for the Crane Iron Co., and found him putting a patch on a perforated platinum crucible. His anvil was a railroad spike, welded to fit the inside of the crucible and driven into a wooden block. The crucible he was using had been repaired repeatedly in this way.

Steel Rails From Sink-Head and Ordinary Rail Ingots

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with great interest the series of papers by Dr. George K. Burgess, "Steel Rails From Sink-Head and Ordinary Rail Ingots," appearing in the November issues of CHEMICAL & METALLURGICAL ENGINEERING. Accompanying editorials were also of exceeding interest, especially that appearing in the issue of Nov. 17, "Why Not Turn the Mold Over?"

There is no question that good rails, or any steel product, is more than a sulphur print, and that Service is the final analysis by which quality must be judged.

The comparative method of conducting the Hadfield and Maryland ingot tests I feel is, however, open to just criticisms in that: First, a similar chemical analysis of steel was not employed. Second, that the more homogeneous and consequently denser Hadfield ingots were rolled in the same number of passes (thirteen) employed in blooming the more open and less dense Maryland ingots. It has been the experience in very many plants which have adopted the turned over, or big-end-up, mold method of producing ingots that the denser steel cannot be reduced in cross-section as rapidly as the more open, less dense ingot, without danger of producing cracks or internal ruptures in the more dense material. Third, that the Hadfield ingots were charged in the soaking or reheating pit cold,

which enhances the liability to surface defects and deep cracks most materially. The relatively large number of "second" rails from the sink-head ingots is unquestionably attributable to this practice of cold charging and heavy blooming passes of the Hadfield ingots.

The exhaustive tests of the Bureau of Standards, as described by Dr. Burgess, have clearly proved beyond peradventure that no physical defects and chemical segregation less than 12 per cent can be assured to the producer and buyer of steel product for at least 85 per cent of the weight of the ingot, whereas in the ordinary type of ingot production, even after cropping 26 per cent from the top of the ingot, defects are apt to occur in the middle and bottom portions of the ingot and in the finished product produced therefrom. I wish to reiterate that faulty heating and blooming of rails and other products can spoil or reduce the quality and homogeneous structure of initially perfectly sound homogeneous steel ingots, and that those who undertake to remedy the present defects in rails and other steel products must look further than the obtaining of an initially sound ingot, although that is the primary requisite. Care in reheating and in employing a suitable number of blooming passes has been found absolutely essential in order that the producer of sound ingots may profit thereby in his finished product.

EMIL GATHMANN.

Electric Furnace Refractories

To the Editor of Chemical & Metallurgical Engineering

SIR:—A reply to the letter written by Robert D. Pike, criticizing certain statements made by the writer in the article entitled "Electric Furnace Refractories," and published in your issue of Dec. 15, may be in order.

Particular exception was taken to the statement in that article that amorphous magnesite was entirely unsuited for the manufacture of refractories. The writer still maintains that the statement is correct and will be borne out by anybody and everybody who has had a wide experience in the manufacture and sale of magnesite refractories made from the raw material from Washington, California, Austria, Greece and Venezuela. It will be noted that the statement was not made that refractories *could not* be made from the amorphous type, but that it was *unsuitable*.

After the Austrian magnesite was cut off by the war this country was driven to the use of the amorphous magnesite of California. No one but the manufacturers themselves will ever realize the amount of effort, time and money that was put forth in an effort to make a product satisfactory to the steel and copper industry from this material. Four years of research and experimental work, combined with the erection of special plants and the installation of special equipment, did not solve the problem and convinced both producers and consumers alike that a satisfactory product could not be made. Furthermore, as soon as refractories made from the crystalline ore became available the consumers refused to purchase those made from amorphous ore.

Mr. Pike is quite right in his statement that the formation of periclase or beta magnesite has nothing to

do with the type of magnesite used. However, the formation of periclase was the stumbling block to the successful use of the amorphous type. Periclase is more readily formed with the crystalline type and the formation begins at lower temperatures. Brick and shapes made from the crystalline can be thoroughly converted to the periclase stage in the kiln before they start to squat or soften out of shape, reaching a point of complete crystallization in perfect condition. When the amorphous is used, however, the formation of periclase does not take place until the critical point is reached, and any attempt to reach a point of complete conversion resulted in losses that the manufacturer could not stand on quantity production. The firing of the product was, therefore, stopped before the critical point was reached and while the magnesite was still in the amorphous stage and an unsatisfactory product resulted.

Mr. Pike is not correct in his statement that the Northwest Co. was the first in the United States to build and operate a plant which produced a true dead-burned magnesite. In 1915 the American Refractories Co. started the first dead-burning plant in this country at Harper, Ohio. Later the Lehigh Portland Cement Co. converted a portland cement plant at Coplay, Pa., and operated it as a dead-burning plant. Following this the Harbison-Walker Refractories Co. constructed and operated a dead-burning plant at Chester, Pa. All of these plants produced true dead-burned magnesite from California amorphous magnesite and all were constructed and operated before the Northwest plant at Chewelah, Wash., was built. It might be added that these plants produced material of the highest possible grade from the material used and were operated by men recognized as being the foremost in the industry.

The real reason for the production of only calcined magnesite instead of dead-burned in California was that there was not and is not any single deposit in California large enough to warrant the establishment of a dead-burning plant, and so long as it was necessary to ship the material from several points, the refractories manufacturers preferred to convert existing rotary kiln plants in the East to dead-burning plants or to add rotary kiln equipment to their brick plants. The magnesite was calcined in California before shipment East in order to save freight, as it loses practically half its weight through the driving off of the CO₂ gas. California magnesite was not "dead-burned," therefore, simply because the users preferred it otherwise and there was never a time when the magnesite manufacturers, or for that matter the ultimate consumers, were confused over the terms "calcined" and "dead-burned."

It is useless to enter into any argument over the relative merits of Austrian and American magnesite. It is quite sufficient to say that in spite of the fact that a considerable tonnage of Austrian has been coming into this country regularly for the past two years, the supply has never equaled the demand and the cargoes have always been sold before reaching this country.

Pittsburgh, Pa.

A. F. GREAVES-WALKER.

A Substitute for Cork

It is reported that a Czechoslovakian chemical works at Brünn has treated turf by a special patented process whereby was furnished a material for insulation and building purposes that is said to be, in most respects, not inferior, and in some superior, to cork. The product is reported to be light, firm and soundproof, to possess great insulating properties, and to be damp-proof.

Kauri-Gum Industry in New Zealand

The kauri-gum industry, which has been an important factor in and around Auckland for the past half century, is taking on new impetus since the closing of the war, reports Consul General Winslow, of Auckland. In the past most of the work was done by hand and by individuals, something like gold was mined years ago in new fields, with the result that the top had only been skimmed over and the better pockets dug out. These methods have secured about \$100,000,000 of kauri gum to date, and it is claimed that there is still left in the kauri field gum and byproducts worth at least two or three times what has been taken out.

GOVERNMENT ENCOURAGEMENT FOR INDUSTRY

Until recently the development of the kauri-gum fields has been left entirely to private enterprise, but about three years ago the New Zealand Government established a department for the supervision and encouragement of the industry, with the result that more extensive operations are being undertaken by companies as well as by individuals. It is now proposed to develop the industry along more systematic and scientific lines than those heretofore employed.

From 12,000 to 15,000 tons of kauri gum will, it is expected, be produced per annum, instead of 8,000 or 9,000 tons, as was the case previous to the war, to say nothing of the byproducts, which are estimated to be worth as much as or more than the gum itself. One company plans an output of 8,000 to 9,000 tons of gum per annum, and there are besides many private individuals at work in different sections of the field, and other interests are contemplating putting in new up-to-date plants.

SLUICE MINING—EXTENT OF FIELDS

The latest undertaking is to mechanically gather the gum from the peat, or pukau, which is really the damaged kauri gum, in the low or swampy land found in the territory around Auckland. This is to be worked by what is known as the sluice process, similar to sluicing for gold. The peat is placed on a screen and water is forced through it. The screen gathers the chip gum and allows the waste or tailings to drop beneath. This chipped gum is divided into about 15 per cent first quality, 15 per cent second quality and 70 per cent low grade. The tailings are converted into kauri-gum oil in a manner similar to extracting oil from shale. It is estimated that 40 to 50 gal. of kauri-gum oil can be taken from a cubic yard of pukau. This oil is a very valuable commercial oil, containing a large percentage of motor spirit and turpentine.

It is stated that one company in Auckland has control of kauri-gum rights covering 47,000 acres, estimated to contain 13,000,000 cu.yd. of pukau. In addition, the New Zealand Government still holds kauri-gum reservations that are estimated to contain an even larger quantity of pukau, to say nothing of many private interests holding small sections of kauri swamps. This will give some idea of the real size of the industry that means so much to the paint and varnish interests of the United States, as well as to the linoleum and rubber manufacturers.

The New Zealand Government is allowing persons to stake out tracts or claims of three acres on the government reservations, for which the individual operators must pay 10 per cent of the value of the gum taken from these swamps.

ISTORIC JACKSON SQUARE. OLD SPANISH CABILDO AT RIGHT

The New Orleans Meeting of the American Institute of Chemical Engineers

Report of the 13th Winter Meeting, Reviewing Salient Features of Papers Presented, With Notes on Excursions to the Union Sulphur Plant at Sulphur, the Salt Mines at New Iberia and the Luray Cavern

THE thirteenth winter meeting of the American Institute of Chemical Engineers took place at New Orleans, Dec. 5 to 9. The paper program was held in the ancient Cabildo. This is a dignified two-story structure of adobe and shell lime, which has stood since 1795 as a monument of Spanish dominion over the Louisiana territory. Not far distant Audubon Park marks the place where, during this same memorable year, Etienne de Boré made the first plantation sugar. Eventually this was to become the primary product of the district and exerted no small influence in bringing about the Louisiana purchase eight years thence by the United States. President David Wesson in the opening address told what the Institute has been, is and should be by starting off with one of his appropriate stories.

•
PRESIDENTIAL ADDRESS

"In the good old days of long ago, when every man of standing in this part of the country had his special body servant, two colored boys were heard discussing their respective masters. The first was bragging about the great wealth his master, who was a rich planter, had accumulated. He ended by saying 'Your boss is always traveling. Don't you know a rolling stone gathers no moss?' the answer came back quick as a flash, 'It sure doesn't get any moss, but it gets lots of polish just the same, and that is what your boss needs.'

"This remark applies in some respects to the Insti-

tute. When we take an excursion like the present one, the railroads remove considerable of our moss, but the inspiration and broadening effect caused by close association with many master minds of our profession engaged in the various fields of industry more than compensate for the time and lucre spent in attending this meeting.

"One of the first objects of the Institute was to bring men together who had made good in their profession, so all might be benefited by mutual interchange of views.

"Another object was the elevation of the profession to a position in the community commensurate with the services of its members.

"Up to a year ago the Institute passed through a slow but steady growth. The high code of ethics and the standing of its members gave it a respected place, but there were not enough of us to do properly the work for which we seemed to be especially fitted.

"Some of our far-seeing members suggested that the Institute would carry more weight in important national affairs if the membership contained all those who were eligible. A modest campaign was started with the result that our total membership today numbers 454 as against 365 of a year ago, an increase of 24 per cent.

"During the past year we have joined the Federated American Engineering Societies, whose object is to secure the co-operation of the prominent engineering societies of the country to utilize their possibilities for constructive work in great public service questions, in

matters of transportation, conservation of natural resources and similar affairs.

"We have given hearty support to the proposed reorganization of the Department of Interior into a Department of Public Works.

"The Institute is backing the compilation of the Compendium of Critical Chemical and Physical Constants, which when completed will furnish a valuable storehouse of information and become a needed tool chest for members of the profession.

"The Institute is also acting to some extent in an advisory capacity to the Government engineers having in charge the survey for the new Boston-Washington superpower project.

"These facts are mentioned to show that at the present time the Institute is not merely a joy ride association, but its activities are of national importance.

"There is no longer any question of the value of the work of the chemical engineers to the welfare of the country. There is, however, the great question as to how it can be made of greater value. We have all seen what organized labor has done through the sheer strength of numbers and organization. Is it asking too

ing, as far as emphasis is concerned, though as a producer or a manager of chemical production he is older than some of these, though not in an organized way. The chemical producer of the nineteenth century was unorganized. His only approach to solidarity came through chemical societies. These were naturally academic and looked down upon the chemical engineer as an empiricist who was neither an engineer nor a chemist. The mechanical engineer felt that he could do all the engineering necessary in chemical manufacturing. On the other hand few chemists connected with manufacturing could resist the temptation to call themselves chemical engineers, though their work was entirely analytical control or industrial research, and though they did not have to deliver the production or put up or operate the equipment. The chemical engineer can do and often does the strictly chemical things too, but on the other hand not all that do this important control and investigational work are engineers.

"The American Institute of Chemical Engineers has played an important part in clearing the atmosphere about what constitutes a chemical engineer. To the speaker's mind all is not as clear as it might be even

AUDUBON PARK

CLOISTER ALLEY

much to have all those who are fitted by education, achievement and high character brought into one strong organization by becoming members of our Institute? With the professional leaders of our chemical industries all working together toward one common end, an enormous influence for good can be exerted upon the material, economic, educational, legislative and industrial affairs of the country. The days have gone by when the Institute was regarded by some as a sort of excursion club for a select few. The day has come when the Institute must take the lead in shaping the thought of the chemical industries of the country, and to do this, it should count among its members all the qualified leaders of those industries. During the past year we have made a fine start. Let us, therefore, keep up the good work of securing desirable members so we may better accomplish the work which lies before us."

THE A.I.C.E. AND THE F.A.E.S.

Prof. James R. Withrow gave a report on the Washington meeting of the Federated American Engineering Societies, which need not be abstracted here, as a full report has been presented in our issue of Dec. 1. His views on the chemical engineer among engineers are reproduced as being of salient interest.

"The American Institute of Chemical Engineers is an organized effort to represent the solidarity of the profession of chemical engineering. The chemical engineer occupied a peculiar position in the engineering profession. His branch is new compared to the others such as civil, mechanical, and even electrical engineer-

ing, for he is compelled every few months to vote against good chemical friends, who are strictly research or control (analytical) chemists and not engineers at all, to his way of thinking, and who stand approved by even our eligibility committee, careful and fair as we must concede it to be.

"However, with this good work done or in progress, it is our part to go steadily forward in assuming the responsibilities of an engineering organization. It was quite natural, perhaps, that during the war the larger group of chemical men, the American Chemical Society, were mistaken by the other engineering societies as their chemical complement. The American Chemical Society should have been taken into all that it was taken into, but the great bulk of its members are not interested in chemical engineering. This Institute should not have been omitted, however. Repeatedly I have had to protest in this matter. Now it would be the Naval Consulting Board, again it would be the National Research Council, again the Joint Conference Committee. Others have interested themselves in this also, to my knowledge. Sometimes I have notified the Institute of my protests and sometimes I have not.

"It is our duty to stress less the chemical and more the engineering. The words of our name make this clearly necessary. Chemical engineering is *engineering*. It is the engineering of chemical productions—not the chemistry of chemical production. That is industrial chemistry—and is *chemistry*, and by no means engineering, though chemical engineering is its handmaiden.

"It is our duty also to weave our web closer and closer to the other branches of the engineering profession. It is here that our future lies. We have at once the most difficult, the most enthralling and the most undeveloped field of the whole profession of engineering.

"Since it is our duty to align ourselves more and more with the engineering profession, our question is, Where shall we begin so as to be of greatest assistance to the engineering profession as a whole, and make the other engineering profession branches respect the dignity of our field? My purpose is to emphasize that we have taken our rightful place as an Institute of Chemical Engineers by joining hands in the public service for America's good, with the other engineering associations in the Federated American Engineering Societies."

ASSOCIATE MEMBERSHIP DISCUSSED

Frank E. Dodge introduced a resolution creating associate membership, which is believed to be more desirable than the present junior grade. No action was taken, and after considerable discussion the motion was tabled to allow time for general opinion to crystallize. Many manufacturing plant mechanical engineers having allied chemical interests and accomplishments are to be included in this class if it is worked out on the tentative basis discussed at the meeting.

LONGWORTH DYE BILL INDORSED

Recognizing the conflicting opinions in Congress toward protecting the dye industry, the Longworth bill was briefly indorsed and the following resolution wired to Washington:

Whereas the American Institute of Chemical Engineers, at the annual meeting at New Orleans, now in session, recognizing the importance of the coal-tar industry to the country at large and the great danger threatening it in case adequate protection is not afforded it by our Government before peace with Germany is declared; therefore be it

Resolved, That we reiterate the position taken at our annual meeting in Savannah in December, 1919, and urge immediate favorable action on the so-called Longworth bill.

SECTION 9 OF NOLAN BILL CONDEMNED

The rider in the Nolan bill, Section 9 of H.R. 11,984, which may be found in our issue of Oct. 27, was condemned as being improper legislation. It was thought that the rider would lead to interference by the Government bureaus with business enterprise with which they were originally intended to co-operate in supplying service of benefit to all.

WELFARE PLANS OF THE DU PONT COMPANY

Charles L. Reese gave an interesting account of the present plans of the du Pont company in protecting the savings of employees with stock investments in the company as well as the presentation of awards of stock for extra compensation whenever merited. During the war some of the employees received an annual bonus as high as from \$30,000 to \$50,000. Invention, bravery, valuable suggestions were all compensated for in adequate manner. Regularity and continuous employment are not overlooked in the stock awards. The complete details will be published in an early issue.

CONSERVATION OF HEAT LOSSES

E. R. Weidlein described the development work done for the Magnesia Association at the Mellon Institute. Calculation charts were given with which the most economical installations are found. When it is considered

that the energy losses of 100 ft. 6-in. uncovered pipe at 100 lb. pressure are about equivalent to 300 tons of coal per year on an average, the importance of 85 per cent magnesia needs no further comment. In discussion Henry Howard recommended combination with felt for low-temperature insulation when condensed moisture would remove the insulating air cells in the usual magnesia insulation. Roofing paper should be applied as protection against water and should not be allowed to become hot, else the flux oils saturate and ruin the insulation.

RECENT ADVANCES IN THE SULPHUR INDUSTRY

In the absence of Dr. Raymond F. Bacon, the paper on sulphur was read by Dr. Weidlein. Two new sulphur domes have been operating recently in Texas, with the result that the supplies of sulphur have been adequate to supply every demand at prices actually competitive with pyrites. Dr. Bacon believes that sulphur should be used as an engineering material, as it has many desirable properties not obtainable readily elsewhere. It can be filled with sand to lower the volume cost. Acidproof conduits have been produced at an extremely low cost from sulphur.

THE SULPHURIC ACID FUME PROBLEM

This was a preliminary paper by Drs. James R. Withrow and F. C. Vilbrandt on their investigation on acid fumes. The literature and legislation were reviewed and the various analytical methods of testing contaminated air critically examined. The permanganate method was found unreliable due to the fact that intermediate reduction products of colloidal manganese oxides were produced. Standard SO_2 mixes were also found unsatisfactory, due to this vapor not forming stable mixtures under all mechanical conditions. For instance, passage through an abrupt angle caused considerable variation in the composition of the air-vapor mixture.

COST ACCOUNTING

Successful plant operation depends on proper interpretation and analysis of costs. A. G. Peterkin presented the manager's point of view. He wants less routine reports and masses of burdensome statistics on costs, with the result that the accounting department will be free enough from routine labor to work up any data upon request at any time. The basic fundamentals on cost keeping were presented, the details of which will be published in a subsequent issue.

SUGAR AND MOLASSES

Lezin A. Becnel presented some interesting charts on cane products showing the relationship between molasses and sugar production. He was very much in favor of less sugar extraction and the consequent production of higher quality sirup byproducts. The price of the latter will be more than sufficient to compensate for the sugar remnant, when compared with the present grades of lesser epicurean virtues.

RESOURCES OF LOUISIANA

A rich soil abundantly irrigated by the waters of the alluvial Mississippi is Louisiana's greatest asset. N. L. Alexander, chief of the State Conservation Commission, gave an illustrated lecture describing the forest and game reserves of the state. About 200,000,000 ft. of lumber is cut annually by the 460 sawmills within the state. Reforestation is rapidly becoming necessary and

anticipating this the state has established a 30,000-acre reservation. Pulpwood of good kraft quality has been produced in fifteen years. The Goodyear Co. is planning to plant an extensive reserve to supply its pulp mills in the near future. Tax reductions are being offered to induce forest planting and lower the investment required. Boys' clubs appear to be especially promising in this direction. The game reserves far outstrip the combined zoos of the world. Ducks, geese and all waterfowl from the entire North American continent appear to appreciate the natural advantages of the state during the winter season.

Sulphur, salt, gas and petroleum have been found in quantity. The two former will be described later. Considerable alarm is felt over the rapid growth in the state of the carbon black industry, which will rapidly exhaust the gas fields and yield very small return to the welfare of the state compared to household consumption. The present law requires all new installations to obtain a state permit, which will be granted in fields located in places remote from towns and cities.

WATER PURIFICATION, SEWAGE AND DRAINAGE

George G. Earle, the engineer who has freed the Crescent City of the difficulties incident to the negative elevation of the city, described the pumping system used to empty the seepage, sewage and rain waters over the levees into the river. Special pumps were designed based on the screw effect which will pass almost any obstruction from an overcoat to a demijohn.

HANDLING CONCRETE MIXES

On large construction work the mixer is usually located as centrally as possible and to facilitate the handling of the mix, a very wet mix is used. Maximilian Toch drew attention to the danger of defective construction due to this and advocated that the engineering profession undertake to improve the present practice. He was not prepared to offer suggestions, but hoped to be able to do so in the immediate future.

ACTIVATED SLUDGE

Edward Bartow gave an interesting lecture on the treatment of sewage by aeration in the presence of activated sludge as developed in England. The greatest problem requiring solution appears to be an economical method of drying the sludge. This contains 90-odd per cent of water, which is removed with difficulty on the scale required. Experiments are now under way that may lead to results at Milwaukee. Where a large area of open country is available and the climate is dry, solar evaporation offers about the most satisfactory way around the drying difficulty.

SALVAGING SAG PASTE

Sag paste is the zinc oxide ointment used during the war as a skin protector against poison gas. C. B. Morey described the method used by the Larkin Co. in salvaging the fatty constituents and the tin in the container tubes. Several million tubes were worked up into merchantable products, the operations for which were of interest due to the way the problems encountered were solved.

DATA ON HORIZONTAL TUBE EVAPORATION

Results on evaporation data are hard to get, due to the multitude of variable factors. Prof. W. L. Badger presented his fourth report in which he worked on

distilled water in a horizontal tube evaporator. The paper will be published in full in an early issue.

VISIT TO UNION SULPHUR PLANT

The Institute Special train arrived at Lake Charles Wednesday morning. The local Chamber of Commerce showed great appreciation of the talents of chemical engineers, undoubtedly being influenced by the accomplishments in their locality of the late Herman Frasch, and not only were prepared to welcome the visitors but banqueted and carried them in their automobiles out to Sulphur, about twelve miles distant.

The area of the sulphur works is about sixty-five acres, studded with derricks similar to an oil field. The great boiler house and multitude of compressed air, hot water and sulphur pipe lines are the distinctive features. The old dome looks more like a lake, due to subsidence of the soil where the millions of tons of sulphur have been removed. Plank roads set on piles interweave through the works. A slight mist of water vapor floats over the ground, but the 750 ft. of earth almost completely hides the presence of the superheated water below.

The blackish-brown molten sulphur is air lifted from the lower levels of the bed into 3,000-gal. open pans, from which it is pumped by centrifugals to the board-framed stock pile.

SALT MINE AT NEW IBERIA

Chemically pure salt is usually obtained only by the aid of chemical technology, but only the arts of the miner are required at the salt domes called Avery's, Weeks, etc., islands because of their elevation above the surrounding flood lands. The beds are of Quaternary age. The crystal structure is such that practically all the mother liquor inclusions have drained off to some unknown locality, which when found will probably give the long-looked-for source for potash and magnesium salts.

The ladies of New Iberia were the hosts. The party was driven out to the rice mill, where the grain was hulled, the bran removed and a polish applied by means of a paste of glucose and soapstone. At the present time a large pulp mill is being erected to utilize the cane bagasse and rice straw of the district.

Refreshments were served at the hotel, after which Toastmaster Williamson called up the speakers. Dr. Olsen in his talk did his best to repay the hosts with a liberal supply of expert advice on salt. He told them that while they were receiving about \$4 per ton for the raw salt at the mine, they were paying about \$140 to the North for the manufactured goods made from this ton of salt. The orchestra finally resorted to dance music and the party ended at a late hour with the refrains of "Home, Sweet Home."

NEW YORK PARTY STOPS OVER IN VIRGINIA

The special car Custer was dropped off at Roanoke so that the party could see the city. The blast-furnace plant of the Virginia Iron, Coal & Coke Co. was visited. The Dwight Lloyd process of desulphurizing pyrite ash proved to be the most interesting feature. From 3 to 4 per cent sulphur is present in the ash as it is received from the sulphuric acid works. This is mixed with powdered coal and ignited on a 60-ft. chain belt grate. Excess air is drawn through the mass, which has been leveled to a uniform thickness of 6 in. Practically all the sulphur is oxidized and the quenched iron and coke

clinker is mixed with local brown and Lake Superior ore to give the analysis required for the blast-furnace charge.

The Luray Cavern, with its unique calcite crystals wrought into amphitheatres, towers of Babel, Castles on the Rhine, Saracen's tent, fish market, scarfs, drapery

LURAY CAVERN

and hundreds of artistic forms, was a fitting sequel to the meeting. The underground chemical plants operated by nature at Sulphur and New Iberia could be much more appreciated after the visit to this subterranean museum of fine art.

ATTENDANCE

French Factory for the Manufacture of Vaseline

Preparations have been made for the erection of a vaseline factory along the Nievre River at Ile-d'Elle, Department of Vendee, where the existence of a clay rich in alumina has been discovered, reports Consul Moorhead, of Nantes, France. New methods employed will produce vaseline at lower than ordinary prices.

Need for Work on Aluminum by Bureau of Mines Pointed Out by Dr. Moore

The Bureau of Mines has requested an appropriation of \$29,920 for work on aluminum. In explaining the need for this work, Dr. R. B. Moore, the bureau's chief chemist, has prepared the following statement:

During the last two or three years the Bureau of Mines has had two men working in aluminum, mainly in connection with aluminum losses in remelting, etc. The small sum available has not made it possible to take up larger phases of the work—namely, the cheap manufacture of aluminum oxide, either in a primary operation or in connection with byproducts, and improvements in the manufacture of aluminum metal itself. Such a line of work will involve a special appropriation which is not now available and will require at least a minimum of \$30,000 to carry out in an efficient manner in so far as the Government is concerned.

Aluminum is one of the most important metals of the present day and its use in the industries and for domestic purposes has only just begun.

In the process of aluminum manufacture, oxide is first produced, the source of the oxide being almost entirely bauxite. By electrolytic methods the oxide is then converted into the metal. Therefore there are two distinct steps involving improvements and efficiency—namely, the production of the oxide and afterward the production of the metal.

At the present time the cheap production of potash from silicate rocks, such as potash, feldspar, leucite, etc., involves aluminum oxide as a byproduct. The possibility of making aluminum oxide from certain types of clays and other aluminum minerals besides bauxite is of extreme importance for the cheap production of aluminum metal. The possibilities of even producing metallic aluminum directly from the aluminum minerals without the intermediate production of the oxide and the after use of electrolytic methods have by no means been entirely exhausted. On the other hand, undoubted improvements could be made in the present electrolytic methods, especially in the way of getting a standardized product.

The use of aluminum has tremendous possibilities in the industries and for domestic purposes. Its alloys with magnesium are receiving at the present time much attention, as such alloys are often even lighter than aluminum.

Duralumin, which is an alloy of aluminum, copper, manganese, etc., is an extremely light alloy but has the strength of mild steel. It has been used by the Germans with great success for a large number of purposes, especially for the framework of dirigibles, for airplanes, etc. The uses of aluminum and its alloys in connection with automobile parts, for domestic purposes, etc., are well known. If the price could be brought down to considerably less than the price at the present time, its uses would be greatly extended.

American Shoes in Switzerland

American shoes are sold in Berne and, in fact, in practically all the larger cities of Switzerland. Imports since the war show an encouraging increase. In that country there are about twenty shoe factories with an output of about 80,000 pairs daily. One factory alone is said to produce 50 per cent of the total output. Because of the development of the industry there is also a comparatively good market for shoe uppers, reports Consul Haynes. The possibility of success would be more probable if stocks were kept in Switzerland, such a system being generally preferred to the presentation of samples. The value of leather imports is about \$4,000,000 annually, the import duty varying, according to quantity and quality of leather, from 77c. to \$4.63 per 100 kilos (220 lb.) gross weight. The duty per 100 kilos is as follows: Sole leather, 16 fr.; box calf, brown, glazed, 24; box calf, black 18; vamp leather, brown or glazed, 10; other upper leathers, 4; other leathers not specified in the tariff, 4 fr.

Ammonia and Benzene Column Stills

Description of Operating Methods of Ammonia and Benzene Column Stills—Action of Steam in Heating and Conveying Vapors—Causes of Trouble and Precautions—Process Control—Recommendations on Liquor Metering

By A. THAU*

FOR the distillation of ammonia and benzene in connection with the recovery of byproducts from coke ovens, continuous column stills are almost universally employed. The original "Savalle" column, which was the first continuous alcohol still, was adopted at first as a progressive departure from intermittent boiler-type stills. Gradually improvements were introduced to adapt the columns to the particular purposes for which they are applied in coke-oven work, and in recent years they have reached high efficiency, while at the same time their bulk in proportion to their capacity has been considerably decreased.

Designers of these stills were formerly rather reluctant in constructing single units for very large capacities. Experience had shown that if particular care was not taken when heating up the stills, the bottoms or flanges of the sections would crack. This danger increased with the diameter of the still. This accounts for the fact that in old ammonia and benzene plants a large number of small units were used, while on modern works few large ones are used and in most cases only one unit.

The control of a badly performing distilling column has always been considered a difficult task, but if the process taking place inside the still is perfectly understood, it is not difficult to allocate and remedy irregularities.

The Savalle column, the principle of which has been retained completely in subsequent design as shown in the figure, consists of a number of circular or rectangular sections, flanged together. While the liquid to be distilled is being introduced into the top section of the column, steam enters countercurrent at the lowest section near the bottom of the still. The steam is distributed through a number of round holes or rectangular slots *a*, the edges of which project about 2 in. above the bottom plates. These steam passages are covered a short distance above the projecting edges by hood-shaped baffles *b*, which project downward close to the bottom or tray *c*. They are provided with small teeth so as to distribute the steam evenly in a fine spray through the liquid which collects on tray *c* of each section.

Tubular or rectangular overflows *d* are provided for each section. Their upper edge does not project quite as high as those of the steam passages *a*. They go down into the next lower section so that their end is sealed in the liquid collected on the bottom. Baffle strips *e* are arranged on each bottom *c* between the baffles *b* in order to compel the liquid to flow over each tray and all around the baffles *b*.

By these arrangements the steam is guided upward and the liquid downward through the column in sep-

arate passages. If liquid travels through the steam passages or steam through the overflows, the operation of the still is impaired, though perhaps it is not immediately noticeable. However, before dealing with such occurrences it will be necessary to follow closely the processes performed in each section.

TWOFOLD ACTION OF STEAM

The steam expands and fills the section completely, thereby directly heating the lower layer of the liquid and indirectly the liquid in the section above. The transmission of the heat through a cast-iron plate of about $\frac{1}{2}$ in. in thickness is much slower than by direct contact. Vapors of products with a lower boiling point are volatilized and mix with the steam. In the bottom section, where the liquid should contain only traces of products, this admixture is naturally relatively small, but it increases from section to section upward, while an amount of steam, proportional to the amount of vapors taken up, condenses. This action

is of minor importance compared with the effect resulting from the steam being forced in fine streams from under the baffle edges through the liquid with which it is thus brought into very intimate contact. The transmission of heat from the steam to the liquid is thereby greatly increased and the admixture of light vapors becomes much greater. It is clear that these actions are parallel in each section of the still, one supplementing the other. In the same degree as the steam traveling upward becomes enriched by vapors, the liquid running down becomes spent.

A different way of describing the direct action in a column still can be applied by assuming that the steam, in passing through the indirectly heated liquid, takes up vapors with a lower boiling point in exchange for water vapor which is condensed and dilutes the liquid. Whether this or the other explanation appeals the more is immaterial, as the actions are due to both. The column still can, of course, be used as a washer and some of the first gas washers ever built were constructed on the very same principle. The gas takes the place of the steam and the washing liquid is fed the same way as for distilling. The only differ-

*Superintendent of coke works and chemical plants of the Oxelösund's Iron Works, Oxelösund, Sweden.

ence from distilling rests with the fact that a chemical or mechanical absorbing effect is obtained without the aid of heat. Ammonia, benzene, cyanogen and naphthalene washers of this type are still used. Though they were formerly built of very large diameters with large gas passages and baffle openings, they are now rarely applied as washers owing to the great amount of back pressure they cause, which also impairs their efficiency.

In the construction of the column still two different tendencies are prominent. Many constructors disregard the indirect action of the steam and provide as many passages, baffles and overflows as can be crowded into the column. Others try to make full use of the indirect heating by the steam and arrange only one steam passage, baffle and overflow to each section so that large layers of liquid are collected in each, offering a large surface to the steam above and underneath. In the former types provision is made to enforce a rapid circulation of the liquid. In the latter designs the liquid is to remain in each as long as possible and flow slowly in proportion to its feed—in an ordinary zigzag way down the still sections. These latter stills, extensively used in England and less in number on the European Continent, form the minority in use. Thus far the action of a fractionating still is the same, whether used for the distillation of ammonia or benzene. It will now be necessary to treat both kinds separately.

AMMONIA STILL

The ammoniacal liquor as it comes from the coke-oven plants contains free and fixed ammonia, the latter as dissolved salts. The stills consist, according to the work they have to perform, of three parts—viz., one to drive the free ammonia, one to liberate the ammonia by substitution of a stronger base in the salts and one to treat the liquor holding the liberated ammonia in solution. These three parts are usually united in two columns and at times in one. The fixed ammonia amounts to about one-third, but the part of the equipment in which it is distilled is generally of the same size owing to the bulk of water handled.

The upper part of the column into which the ammonia liquor is fed must be large enough to give the capacity needed to drive off all those compounds which are liberated by the application of heat, mainly ammonia, carbon dioxide and hydrogen sulphide. The liquid leaving this part of the still should contain only traces of free ammonia and no carbon dioxide. The sulphur compounds can be disregarded. Carbon dioxide, which is always present in crude ammonia liquor, is too often neglected and the detrimental part it plays in the operation has escaped proper attention. Though easily volatilized between 90 and 100 deg. C., it condenses, thus going into solution again with the ammonia liquor in the still. Pressure in the still has an impeding influence upon the liberation of CO₂ by heat. The presence of carbon dioxide in the liquor can be ascertained by adding a solution of calcium chloride to a sample which in the presence of CO₂ gives a calcium carbonate precipitate.

While the principles of a column still have been sufficiently described in general, there remains to be mentioned the so-called dephlegmating, a cooling action, which continually takes place on the inner walls of the sections above the liquid levels. As the steam introduced at the bottom is the only source of heat, it

follows that the bottom is the hottest part of the still and by the loss of heat through radiation as well as by the introduction of the liquor at the top, the temperature gradually decreases. This dephlegmating action is important in stills built for direct action, inasmuch as a large portion of the steam is condensed. The vapors are more saturated with ammonia the higher the column is relative to the heat added by the steam. In those stills in which the indirect distilling actions are more pronounced than the direct ones, the vapors are altogether richer in ammonia. In order to retain the indirect heat as much as possible, it is often desirable to counteract dephlegmation, by which the efficiency in this case is impaired. Such stills are covered with a magnesia-asbestos cover.

USE OF MILK OF LIME

To liberate the fixed ammonia, the liquor leaving the top portion of the still enters a mixing chamber in which a strong base alkali, usually milk of lime, is introduced. The lime does not react with the free ammonia, but it replaces the ammonia in its salts and liberates it. If the liquor contains carbon dioxide, it enters into combination with the lime, forming carbonate of lime, which sets stone hard in the still and makes frequent cleaning of the still necessary. For this reason it is advisable to have the liquor free of CO₂. The most certain way to avoid the formation of a stone precipitate is to decarbonate the liquor before it enters the still. One way is to provide a preheater of any effective type, as a heat exchanger warms the incoming liquor by the outflowing waste liquor to a temperature over 90 deg. C. If from lack of efficiency this is not attained, a steam coil must be added. A pipe from the top of the heater is connected direct to the ammonia gas main of the still through which the liberated CO₂ is permitted to escape without entering the still. This pipe must be erected higher than the liquor feed pipe of the still and a feed valve for the liquor arranged on the heater inlet, otherwise ammonia liquor from the heater would be introduced into the ammonia steam pipe.

The milk of lime fed into the still should be kept at a constant strength, generally 10 to 15 deg. Bé. (15 to 23 deg. Twaddell, 1.07 to 1.1 specific gravity). It must be free from large pieces which are not easily suspended in water. It always pays to take care in the preparation of the milk of lime. The lime should be slaked and the solid parts which do not pass a fine grid removed. It is then stored in a receptacle where the water can drain off gradually to thicken. After that it is washed through a very fine sieve into the stirring tank, from which it is pumped to the still. An ammonia distilling column can with the above precautions be kept going for years without being dismantled. If the efficiency decreases, the hand hole lids of those portions of the still in which limed ammonia liquor is treated are removed and the internal parts cleaned by flushing with water at fairly high pressure by means of a hose and nozzle. A well-designed ammonia still, baffle hoods, overflow passages must be proportioned in size so that these removable parts can be taken out through the hand holes for cleaning, inspecting or replacing.

The lime-mixing chamber of the still must be provided with a drain cock of sufficient diameter to drain any lime sediments formed between shifts. A funnel-

shaped mixing chamber bottom with drain cock in the middle has been found most suitable for keeping the lime chamber permanently clean. To compensate for the lowering in temperature by the introduction of the milk of lime, a small steam pipe is brought into the lime-mixing chamber immediately above the bottom and the required amount of steam to supply the heat needed is allowed to enter. The steam pipe is arranged inside the lime chamber as a perforated coil to obtain sufficient agitation to prevent the lime from settling out. The end of the lime feed pipe is advantageously connected to the pipe through which the ammonia liquor enters the mixing chamber from the section above it, preventing the dip pipe from getting obstructed and at the same time insuring thorough mixing of liquor and lime.

The part of the still for treating the limed liquor overflowing from the lime chamber does not call for special remarks. It is advantageous to have this column standing alone at the side of the other, although more floor space is taken up. If it becomes necessary to dismantle a still, the lime still usually needs the cleaning and repairs and for this reason it is better to have it as a separate column.

The waste liquor outlet should be provided with a float valve so that the steam is automatically prevented from escaping through the waste-liquor pipe. The same result can be attained if the waste liquor is passed through a heat exchanger countercurrent to the incoming ammonia liquor. The waste liquor outlet of this apparatus must then be arranged at a height to keep the bottom section of the still sealed.

OPERATING PRECAUTIONS

As the pressure inside a still is very low, only very delicate gages can be used. If the still is shut down without closing the cock of the gage, it will be ruined by the vacuum created in the still after the condensing of the steam. It is much better to provide the steam-inlet pipe of the still with two valves a short distance apart. A high-pressure steam gage is connected between the valves. The lower valve is set according to the steam requirements of the still and the upper one is opened to show a certain pressure on the gage which, of course, is much higher than the actual pressure inside the still. With the upper valve the man in charge has to compensate for variations in the steam pressure by keeping the pointer of the gage constantly at the mark. The bottom section of the column and the lime-mixing chambers are provided with water gages, and from their readings the operation of the still can be judged to a certain extent.

If a new or empty column still is started up, the steam must be applied slowly to warm up all parts gradually to prevent an uneven expansion of trays, mantle and flanges, which are apt to crack easily if suddenly affected by great changes of temperature. The steam condenses and the water fills the trays and seals the overflows. It should take at least four hours to warm up a cold still of average size. As soon as a thermometer immersed in the ammonia steam main shows about 100 deg. C., the liquor-feed cock is opened and the lime pump started. Liquor feed and steam supply are gradually increased as long as the waste liquor does carry recoverable ammonia. The ultimate analysis should not show above 0.005 per cent NH_3 . The liquor in the water gage of the lime chamber should

remain steady and at its proper level. The quantity of steam admitted to the lime chamber must be just enough to compensate for the cooling by the introduction of the milk of lime to keep the liquor boiling gently. Too little steam in the lime chamber makes itself conspicuous by a rattling noise with which the steam enters the liquid. A surplus of steam causes the contents to boil over. It is indicated on the water gage of the lime chamber and may cause the whole still to boil over all of a sudden.

CAUSES OF TROUBLE

Bad operation of a still makes itself felt in three ways: 1. The ammonia vapor is too weak, containing too much water. 2. The still boils over. 3. The waste liquor is too rich in ammonia with normal liquor feed.

An excess of steam compared with the liquor feed must first of all be looked for, especially when the ammonia liquor is as weak as 0.6 per cent NH_3 . If steam supply and feed are adjusted in proper proportion, there is a possibility of a tray having become leaky so that baffles and overflows of one section have become unsealed. No water is obtained from such a tray when opening the hand holes. It also happens that with a faulty still the baffle edges do not reach far enough down. In such a case the still should be increased in height by adding sections. An improvement can be made by placing a dephlegmator over the top section and pass the ammonia through the dephlegmator pipes round which cooling water circulates. The writer had a singular experience in this connection when called to a plant to restart an ammonia still which would not operate properly, although it had been cleaned thoroughly and had even been dismantled completely for thorough inspection. After the first failure the still was opened and it was found upon removing the hand hole lids from the top section that the condensed water vapors did not run straight down outside the column, but congregated along the edges of the flanges before they fell down. This indicated that the foundation of the column had given way on one side. Although the malalignment was so slight that it could not be noticed with the eye, it had caused the overflows on one side of the sections to become unsealed and the steam traveled upward without passing through the liquor.

If the ammonia vapor is too weak, the still is either overfed and must be restarted with less pressure (otherwise an overflow results) or else the waste liquor outlet is sure to be obstructed. The latter obstruction can be detected by the water gage of the bottom section being filled completely. If the water gage on the lime chamber shows an abnormally high level, it indicates that the overflow pipe from the lime chamber to the lime still is obstructed. If both water gages should remain normal, the dip pipe by which the liquor enters the lime chamber from the section above is obstructed. This can quickly be ascertained by draining the lime chamber a little, reducing the level in the gage. If, on opening the liquor-feed pipe to the still, the liquor stands at its old level, the dip pipe is open and the obstruction must be found higher up.

An obstruction in the upper sections of the column can almost always be traced to the first overflow of the top section and is due to tar having been mixed with the liquor. The light oils of the tar distill over with the ammonia and their residue collects as a

soft pitch under the overflow, gradually obstructing it. This can also be avoided by preheating the liquor to its boiling point. If the tar comes in great quantities, it will be carried further down and meet so high a temperature in the lower sections that it will flow right through the still, if it is not carried away in lime deposits.

If, in a properly adjusted still, the waste liquor contains too high a percentage of ammonia, this is due to the still becoming dirty. Lime sediment deposits around the baffles so that the steam is not divided into fine streams when passing through the liquor, but finds its way through large openings. The remedy is obvious.

When liquor heat exchangers are employed, a leak in the ammonia lime, which is under greater pressure than the waste liquor, allows ammonia to pass into the waste liquor. An easy way to discover this is to throw a small quantity of fluorescein, about 10 g. per ton of liquor, into the high level ammonia liquor tank and stir it up so that the liquor gets an even fluorescent green color. If the preheater leaks, the color will be found very quickly in the effluent waste liquor, as the coloring power of this aniline dye is so intense that it can be traced with the eye in minute quantities.

BENZENE STILLS

What has been said about the ammonia stills also applies to a certain extent to benzene stills, which in principle and in design of the single sections correspond exactly with the ammonia stills.

Benzene stills are built in single columns and consist of sections of equal design right through. Dephlegmating action in the still itself is not desired. As the oil enters the top of the still at a temperature at which the vapor pressure of the benzene is high, such columns must be well covered to reduce radiation as much as possible. There must be as many steam passages and baffles on each tray as can be arranged and dead spaces must be avoided.

To obtain the best heat economy, the incoming rich oil first passes through a tubular heat exchanger in which it absorbs the heat of the benzene vapors leaving the still. It then circulates through a second heat exchanger, absorbing the heat of the effluent oil. Then it passes through a preheater with steam coils or specially shaped heating elements offering large heating surfaces, from which it is charged into the still. By these means a low steam consumption in the still is obtained.

A benzene still rarely gets out of order or obstructed. The oil does not deposit solids while in the still. If the liquid boils over, it is due to overloading, a sudden increase of steam pressure or water in the oil. For proper operation of a benzene still, it is important that the effluent oil leaving the still should contain only traces of benzene. It should leave the still at a temperature not below 150 deg. C. to be sure that it is not contaminated with water, which decreases its absorbing properties and increases the steam consumption in the still.

Most of the benzene column stills work only with direct steam, which should be superheated to prevent too rapid condensation, allowing the condensed water to mix with the oil. Some builders provide a few of the sections with steam coils, thus reducing the amount of direct steam and decreasing the chances of getting watered spent oil.

The benzene still designed by Dr. Gasser has tubular sections which are horizontally placed one above the other in a scaffold of joists and are connected by pipes. The oil has to make a round trip horizontally through each section, and flows over a steam coil all the way downward through all the sections. Just enough direct steam is let into the bottom section to accelerate the distilling action. With such a still it is very easy to keep the oil free from condensed water. The steam consumption is considerably lower than with the ordinary column still. The sections, being arranged in single units above one another, are easily accessible. Also it is possible without difficulty to redistill the crude benzene continuously and recover the heavier products, toluene, xylene, solvent naphtha, etc., as separate fractions at the same time.

CONTROL OF COLUMN STILLS

Control of the column stills is had by adjusting the steam consumption, the amount of liquor or oil passing through, the steam pressure, temperature and composition of the effluents.

The waste of steam with continuous ammonia stills can be considerable before being observed. In large plants or where steam is generated directly by fuel, a steam meter should be connected into the steam lines leading to the stills. There are a number of reliable steam meters on the market which are too well known to call for a description in this connection.

Ammonia liquors should be passed through a meter of the piston type, as wheel and propeller meters are not as reliable, are too sensitive to changes of temperature

and too easily get out of order or become obstructed by tar and naphthalene deposits. The flow meter shown in section in the figure is a simple, cheap and reliable device which is not generally known and is equally adaptable to ammonia liquor, oil or benzene. It consists of a valve-shaped body *a* with a tubular seat *b* which is slightly tapered inside. In the center of the tube *b* a spindle *c* is rigidly fastened and screwed into the bottom of the valve body. Over it a tube *d* slides vertically, to which is fastened on its lower end a valve cone *e*. The tube *d* projects on top into a gage glass *f* fastened by a lower gland *g* and an upper one *h*, the latter being provided with a vent cock on top. Behind the gage glass an enameled scale is arranged, graduated in liters or

gallons per hour. The feed cock is arranged on the outlet end of the meter. The liquor, oil or benzene passing through the meter lifts the cone *c* in proportion to the amount of liquid passing through, and the top of the tube *d* indicates on the scale how much feed is applied.

The advantage of the instrument rests with the fact that the movement of the indicating tube *d* is not impaired by a gland or similar guide, but moves freely in the glass tube, which is under the same pressure as the inside of the meter. The instrument is also built in another type in which the scale is arranged underneath the valve body and the indicating spindle protrudes thereby through the bottom downward. The meter must be arranged with a bypass so that the still need not be stopped should the gage glass break. As brass is quickly destroyed by the corroding effects of ammonia upon copper, these meters are made entirely of iron for use on byproduct plants.

Steam pressures are read on ordinary steam gages with large dials; recording gages are rarely used on stills. Temperatures are of the greatest importance. To make sure that the temperatures are actually read and observed by the men in charge, the use of mercury steel tube thermometers which have dials exactly like steam gages are recommended. Excepting the rigid types, they offer the further advantage that they can also be supplied with flexible connection between indicator and mercury stem. The mercury stem is immersed in any remote corner or up on top of a still or main, while the indicator, which is connected to the stem by means of a flexible capillary wire, can be fixed in a convenient spot where it can be continually seen. This makes it possible to arrange all the thermometers belonging to a benzene or oil still in one row so that the operation of the still and the attached apparatus can be observed at a glance. Where it requires special attention to keep the spent oil at the required temperature the outlet thermometer of the still should be arranged for indicating and recording at the same time.

Production of Oil From English Shales

An interesting report upon the shale deposits underlying the county of Norfolk, England, has recently been issued, reports Consul General Skinner, of London. The shale is said to be found at shallow depths and can be delivered at the principal works at a cost of 5s. (\$1.21) per ton. The yield of a good quality of crude oil by means of treatment in specially designed retorts is reported to be satisfactory, and the nearness of the deposits to the surface makes possible the removal of the overlay and the excavation of the shale by means of mechanical diggers.

Two commercial seams of shale have already been opened up and are at the present time available for production, though a number of other shale seams have been disclosed beneath these in boring operations to test the full depths of the shale deposits.

The upper seam is a hard, well-laminated body of shale 8 ft. thick, having two small bands of "blaes," or less hard and laminated shale, intercalated with its other members, respectively, 6 in. and 5 in. thick. The whole seam, including these bands, can be classed as rich commercial oil shale. Variations in physical properties and chemical composition naturally occur in a seam of this thickness, and these differences have been carefully noted and analyzed.

The lower seam is 8 ft. thick. Its roof is 37 ft. from the surface and its base rests on a band of pyrites at 45 ft. which forms a good hard floor. This is a good mineable seam, being composed of a black shale 4 ft. thick, and a lower 4-ft. seam of hard, dark-green shale.

OIL CONTENT

The oil content is present in a dual form namely, in a state of free oil absorbed from some source of liquid oil beneath or in juxtaposition to the beds affected, and, secondly, in the form of a heterogeneous material of unknown origin, indigenous to and probably deposited along with the other elements of the shale at the time of its inception.

The yield per dry ton of shale treated is stated to average 33 gal. of oil content, from which may be recovered 7 gal. of gasoline, 9½ gal. of kerosene, 9 gal. of lubricating oil, with a bituminous residue of 50 lb., equivalent to 5 gal.

METHOD OF TREATMENT

The report referred to also contains the following particulars in connection with the retorting methods employed for the extraction of the oil:

Shale must be distilled at a comparatively low temperature in order to obtain and preserve both the liquid oil and solid products, the resulting incondensable gases being used for heating the retort. In the case of a rich shale, the lower the working temperature the greater is the quantity of light spirit and the less gas.

In the early days of the Scottish shale-oil industry the original retorts were of the horizontal type, like those employed in gas making, but these were rapidly discarded and the vertical type universally adopted. In these vertical retorts the shale is fed into the retort from the top and exposed to a gradual increase of temperature, by which means the light, medium and heavy oils are released in rotation. Access of air must be avoided in order to prevent burning the oil, with consequent production of gases. In practice, it is found that steam protects and helps to carry away rapidly the oil as it is formed, and at the same time it increases the yields of all grades of oil as well as of ammonium salts. In the development of the Norfolk shales toward commercial production it has been essential to devise special methods of retorting. The suitability of these methods is dependent upon factors inherent in the shale itself, and, consequently, foreign to the specific needs common to the shales of other and older fields.

It was the appreciation of these necessary departures from ordinarily accepted retorting practices that ultimately led to the design, construction and operation of a special retort which not only gives a yield of oil above that obtained in the ordinary laboratory retorts, but, on fractionation, the crude oil from this retort separates into spirit, kerosene and lubricating oil equal in quality and percentage quantities to those obtained from the crude oil of the laboratory tests. Further, the scrubbing of the gas (which was not attempted with the laboratory retorts) has yielded, a further substantial percentage of light spirit.

With regard to the question of the yield of ammonia from the shales, various tests have been made of core samples of the upper seam, and the average yield of sulphate of ammonia over the whole thickness of the seam was 22.6 lb. per dry ton of shale. The nitrogen content, running as high as 0.75 to 0.95 per cent, has formed other organic substances, such as pyridine.

The German Vegetable-Fiber Industry

THE attention of textile men in Europe and elsewhere is being attracted to the remarkable results being attained in Germany in the manufacture of yarn from grasses, plants, leaves, etc., reports H. W. Adams, representative of the Department of Commerce in Germany. This new German industry is centered in the plant of the Deutsche Faserstoff-Gesellschaft (German Fiber Material Co.) located in Fuerstenberg, in Mecklenburg, Germany.

This plant was established in 1912. During the first year in which it was in operation it confined its activities to the manufacture and sale of the fibers. In 1913 spinning machinery was set up, and since then the spinning of yarn from these fibers has been carried on on an ever-increasing scale. During the eight years of its existence the products of this concern have covered a wide range of vegetable fibers, including China grass, Australian seaweed, jute, old jute rags and shoddy worsted yarn. Besides the above-mentioned fibers a number of others were worked up during the war by the same firm and extensively used in the various lines of the German textile industry. Some of these fibers were abandoned after the war, owing to the fact that the supply thereof to be found in Germany was not sufficient to warrant their permanent use. Among these fibers are to be mentioned nettle, hops, willow bark, pine needles, cornstalks, ginseng and asparagus. It has been found that the fiber taken out of pine needles and cornstalks can be readily used in the paper mills, it being possible to produce a very strong and tough paper therefrom.

Prior to the outbreak of the war the Deutsche Faserstoff-Gesellschaft was able to secure sufficient supplies of China grass, Australian seaweed and jute, and it focused its efforts on these fibers. During the war the importations of this raw material were cut off and have not as yet been resumed. Since the close of the war this concern has confined itself mainly to the manufacture of yarn from old jute rags.

WIDE FIELD IN USE OF SOLIDONIA IN WOOLEN INDUSTRY

The vegetable fiber derived from China grass is known as solidonia. It is similar to ramie, which is known and used in the United States. The Deutsche Faserstoff-Gesellschaft by means of a special process produces a long, fine, soft and curly fiber. The curliness of the solidonia fiber presents a special feature. This fiber looks very much like wool and mixes readily with that product, thus opening a wide field for its use in the woolen industry.

This solidonia fiber was introduced into the United States shortly before the outbreak of the war and was taken up by various textile industries, especially by concerns manufacturing woolen goods and underwear. German textile experts assert that solidonia is of special importance for use in the manufacture of underwear, as it serves to prevent the garments from shrinking.

In Germany solidonia gained a wide field of use on account of the shortage of wool during the war. As a substitute for linen, solidonia has been used in Germany for the manufacture of table linen of beauty and strength. It has also been used for machine belting. German hosiery and underwear mills have produced from it socks and stockings which are difficult to tear,

unshrinkable underwear and sporting jackets of fine quality and strength.

The German woolen mills have manufactured an army cloth which, composed of 75 per cent wool and 25 per cent solidonia, it is asserted, surpasses in tensile strength any pure-wool cloth. Similar results are claimed with respect to paper-makers' felts, which, with a percentage of solidonia mixture, show a considerable increase in strength. Furthermore, women's and men's clothing composed of half solidonia and half wool or shoddy, especially in piece-dyed goods, have found a welcome on the market. In textile circles in Germany it is declared that there is an unlimited field for the use of this fiber. Prior to the war the price of solidonia in Germany was two-thirds the cost of good staple wool. No actual comparison can be given at the present time, as none of this raw material is coming into Germany. In 1914 solidonia in the carded stage found a ready market at 30c. a lb., delivered in New York or Boston.

SPLENDID RESULTS OBTAINED IN USE OF POSIDONIA FIBER

Another fiber from which the Deutsche Faserstoff-Gesellschaft has obtained splendid results is the fiber known as posidonia. This is also a vegetable fiber. It is derived from seaweed which is dredged in Australia and cleansed and washed in sweet water. Brought to Germany, the fiber is subjected by this concern to a chemical treatment for the purpose of softening it and making it resilient, the original fiber being stiff, harsh and brittle. The staple of this fiber is declared to be equal to a medium staple wool, and it is spun on the worsted and woolen system. This fiber is characterized by an elasticity and springiness, and the cloth which is made out of pure posidonia appears to show scarcely any creases. German cloth mills have mixed posidonia with wool or shoddy, and cloth of good strength and appearance has been obtained. German textile men believe that this fiber, by reason of its springiness, will have a wide field of use in the carpet industry. This fiber sold at half the price of shoddy before the war. Since the war none of this raw material has been imported into Germany.

UNUSUAL RESULTS OBTAINED WITH JUTE

The principal way in which jute has been employed in the United States is in the form of cheap lining and burlap. The Deutsche Faserstoff-Gesellschaft has accomplished some unusual results with jute. By a special process of chemical treatment a long, fine and beautiful fiber is being produced therefrom, a fiber which can readily be spun on the worsted system, pure or mixed with wool.

This same concern has secured fine results from old jute rags, which are being cleansed and made into shoddy, which also can be spun on the worsted or woolen system.

The inventor of all the processes has been the managing director of this company's plant since its establishment in 1912.

This plant began work with a total of fifteen employees. Its personnel now numbers over 250. The buildings have been enlarged and new ones erected, and plans are on foot to make still greater additions. The output of this plant is 10,000 lb. of treated fiber per day of eight hours. The worsted mill is now continually working, being operated in three eight-hour shifts.

Defects Arising in Steel During Fabrication

Microscopic Appearances Caused by Surface Defects, Cold Working, Overheating, and Burning—Nuclei of Fatigue Fractures Are Associated With Phosphorus Bands—Photographs of Changes in Structure During Annealing of Steel Castings Are Also Given

By AUSTIN B. WILSON

GENERALLY speaking, by "defects in steel" it is understood that those defects which can be avoided by the employment of the proper practice are meant. The effects of almost all defects can be more or less mitigated in some way and in many cases entirely eliminated. There are, however, some defects which cannot truly be regarded as such, since, although their presence is not desirable, they do not under favorable conditions exert a marked influence upon the behavior of the metal. "Defect" in reality should be used to designate only those substances or conditions in the metal which make for failure in service.

It is possible to divide the defects which cause early failure into two great classes—defects due to errors in chemical composition and defects due to the treatment of the steel during the process of manufacture. Of these two great classes the latter is undoubtedly the one of greater importance inasmuch as it is the one more frequently met with.

The errors of the first class are due as a rule either to errors in the original charge or from reactions which occur during melting and refining.

Unsuitable mechanical properties are the direct result of larger errors in chemical composition, but this phase may here be entirely disregarded, as this is not in reality a defect in the material, but rather an error in the choice of metal to be used for the particular purpose. Such a case would be the selection of medium carbon forging steel for use as a watch spring.

LOCALIZED CORROSION

Larger chemical errors may also produce an undesirable tendency toward corrosion. As it is highly

improbable that a cheap and practical method of producing an incorrodible iron or steel will ever be found this phase may also be quickly passed over. On the question of corrosion there are two schools about equally divided. One claims that corrosion is purely electrolytic and takes place only by means of small galvanic cells formed by impurities. The other asserts corrosion is due to direct oxidation of the iron by the oxygen of the water. The former attempts to prevent corrosion by use of very pure iron. The latter, while admitting that pure iron commences to rust less quickly than does steel, claims that once the corrosion has started it takes place with equal rapidity.

Whatever the mechanism and theory of the process of corrosion may be, it is certain that some impurities heighten the tendency in this direction. Figs. 1 to 4 illustrate this very well in the case of tinplate which contained pinholes in the tin coating. Fig. 1 is the top of a can upon which a number of pinholes can plainly be seen. After photographing, this can-top was cut up and microsections were taken through and near to some of the pinholes shown. Fig. 2 shows a particle of silicate slag near the surface of the steel base which has not started to corrode, although it can readily be seen that the tin coating is perforated. Fig. 3 is another spot very close to the former where corrosion of the steel has just set in. Fig. 4 is from another specimen showing corrosion in the last stages.

The reader may well ask for further explanation of the above phenomena before proceeding. To begin with, the pinholes in the tin coating are due to the evolution of gas caused by raising the temperature of the steel in the tinning process. This gas, it has been con-

FIG. 5. NONOXIDIZED CRACK IN HEAD OF RAIL.
UNETCHED. $\times 200$.

clusively proved, was absorbed during the pickling just prior to the tinning, and the presence of slag is known to favor this absorption. The iron of the base being electro-positive to the tin, as soon as opportunity offers a galvanic action is set up at and through the perforations in the tinplate, the iron going into solution in preference to the tin and the steel rapidly corroding away. This corrosion can be diminished by the making of cleaner steel—i.e., steel free from slag and oxide inclusions.

Errors in composition of less magnitude are a greater menace in steel than those just described. In case there results metal of unsuitable mechanical properties the error is soon discovered, but in cases of smaller chemical errors it frequently occurs that the defect is not found until it has caused irreparable damage. These smaller errors may lead to the formation of brittle impurities which are suspended or mechanically entrapped in the steel or to the formation of brittle intercrystalline envelopes which destroy the cohesion of the metal. Not all impurities, however, are mechanically held. Some, such as phosphorus, enter into solid solution with the free ferrite which is present and thus affect its ductility to a great extent.

In connection with the smaller errors mentioned above it might be well to refer in particular to the alloy or "special" steels. In heat treating this class of steel a slight error in composition may give rise to vastly different mechanical properties than was expected from the particular thermal treatment employed.

Practically the only possibilities of defects in chemical composition which are of sufficient importance to be given consideration are those which arise from the incomplete removal of phosphorus, sulphur and other undesirable elements. It is too well known to require more than a passing reference here that abnormal amounts of phosphorus and sulphur are the cause of "cold-shortness" and "red-shortness" respectively.

DEFECTS DUE TO IMPROPER HEATING

In considering the defects which are caused during fabrication it is well to begin with those which may originate during the casting of the metal or even prior thereto. Cracks, segregation and non-metallic inclusions originating in poor practice in teeming, or to events happening during solidification of the metal, have already been briefly noted by the author in an

article appearing in *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 23, page 1,161, Dec. 15, 1920.

Defects originating in the hot-working will now be considered. Under this heading fall all operations such as forging, rolling, pressing, hot stamping, etc.—in fact, all operations in which the steel is worked at temperatures exceeding or very close to its critical point. These defects are entirely under the control of the steel-maker and can usually be traced to either carelessness or ignorance.

It sometimes occurs that through some inadvertence, possibly the breaking of a pyrometer thermocouple, possibly non-uniformity in the heating of the furnace, one piece or perhaps a certain portion of a piece is heated to a temperature much higher than the rest. This causes the metal at that spot to become weak and brittle and, should the piece be subjected to mechanical working, might cause the formation of internal cracks or fissures which would be revealed only upon failure. In Fig. 5 is shown an internal crack found in the head of a rail. This crack, unlike a crack exposed to the oxidizing influence of the air, was found to be free from oxide and probably originated as just explained.

COLD-WORKING

Finishing at too low a temperature or "cold-working" induces "strain-hardening," which, although sometimes permissible, often leads to very serious results. Where this strain-hardening is used merely to stiffen small articles not to endure any great stress it serves its purpose well. It frequently happens, however, that cold-worked materials, for instance bolts or rivets strain-hardened in forcing into place, are called upon to sustain important loads and at the same time are subjected to alternating stresses. Experience has proved that strain-hardened metal is particularly unreliable in such cases. It is wise to avoid the use of cold-worked metal where important loads must be borne.

Frequently cold-working occurs through ignorance or carelessness in engineering construction, for instance cases such as forcibly "setting" pieces which do not fit properly or correcting small irregularities in shape by hammering. In tank building bolts and rivets are often hammered until quite cold, although it is an established fact that a rivet with a distorted structure corrodes much more rapidly under certain conditions than does a well-annealed rivet.

In a few cases, notably that of cold-drawn wire, strain-hardened metal is quite reliable as far as strength is concerned, but even the increase of elastic limit so caused does not accomplish much in preventing failure from fatigue. Fig. 6 shows the badly distorted microstructure of a severely cold-drawn wire which gave poor service as an automobile wheel spoke. Fig. 7 shows a finer, more uniform and much less distorted structure in a wire of exactly the same composition. This structure was obtained by "patenting," a form of heat treatment which gives to wires a fine, sorbitic structure. This wire gave good service, and although of slightly lower elastic limit far surpasses the former in resistance to fatigue.

Too severe cold-working also causes defects other than those mentioned above. These are defects which are discovered during fabrication and which merely result in scrapping. The author has in his possession a wire which has been overdrawn so severely that numerous checks have occurred throughout its length.

Cold-working of steel results in leaving the struc-

ture of the metal in a distorted and strained condition. It is generally accepted, however, that cold-working does not permanently damage the metal as long as the tensile strength continues to increase. Fig. 6 as well as Fig. 8, a low-carbon wire, illustrates typical cold-drawn and therefore severely distorted wire. Although it is less frequently a cause of defects than its opposite,

trains at a high speed. If worked unequally different portions may recrystallize at different rates on annealing, thus causing cracks. This, however, is not so likely to occur in steel as in certain non-ferrous alloys.

An excessively rapid deformation of the metal even when at a sufficiently high temperature may likewise result in cracks or checks. No examples of these are necessary, as they are illustrated by photomicrographs illustrating other defects, their appearance depending upon their exposure or non-exposure to oxidizing influences.

DEFECTS DURING HOT-WORKING

For forging an ingot should be at least twice as great in cross-section as the finished shape. It sometimes happens, however, that through a desire to effect economy in the forging operation a smaller ingot is used. This results in a very superficial working of the metal. After forging the structure will be very non-uniform, the metal near the surface being fine grained, that near the center being coarse and brittle.

In addition to the foregoing there are several more or less minor defects which are formed during hot-working. Among these are the laps, seams, etc., due to the partial welding of portions of the metal which have become overlapped during the rolling or forging. Fig. 10 is an instance of this. Another defect in this class is the rough, uneven finish caused by scale, etc., on the surface being rolled into the metal (Fig. 11). The former defect should be weeded out by careful inspection.

10

11

Fig. 10. Lap in nickel steel forging. Etched with picric acid. X 50.

Fig. 11. Scale rolled into surface of sheet. Unetched. X 100.

too drastic working is likewise dangerous in cases where the additional hardness and strength imparted by the cold-working is relied upon.

An example of a very superficial cold-working is shown in Fig. 9, a photomicrograph taken just under the bearing surface of a rail—i.e., at a point which has been subjected to the severe cold-working of heavy

FIG. 15. CROSS-SECTION OF RAIL SHOWING TRANSVERSE FISSURE IN HEAD WHICH CAUSED FAILURE

tion before the material is allowed to leave the plant. The latter may be prevented only by carefully blowing the scale from the surface of the metal before it enters the rolls.

Although often confounded and spoken of as one and the same, there is a great difference not only in the structure but also in the properties of "burnt" and "overheated" steel. Steel that has been "burnt" has been heated above the point of incipient fusion and cannot be restored short of remelting. It is both "cold-short" and "red-short." Its cohesion has been destroyed,

and is well known as granular pearlite or spheroidized cementite. The tendency toward this structure is heightened by the presence of any free cementite.

The results of heating in an injurious atmosphere are too well known to need more than passing mention.

HARDENING TROUBLES

In quenching defects may be caused by any of several conditions. If carried out from too high a temperature a coarse martensitic structure is formed which is exceedingly brittle. If from too low a temperature nothing is accomplished. The quenching effect must be nearly equal throughout the entire piece or severe internal stresses may be set up, often sufficiently great to cause immediate cracking. The quenching medium plays an important part, some quenching mediums giving much more drastic effects than others.

Defects arising from improper tempering may likewise be summed up in a few words. Tempering at too high a temperature undoes all the work of the quenching. Tempering at too low a temperature leaves the steel more brittle than is desired and does not remove enough of the effects of quenching. Tempering unevenly throughout results in severe internal strains, as in quenching non-uniformly.

FATIGUE FAILURES

Before closing, the author would like to call attention to a class of failure which is due usually to some inherent defect in the steel. These are the "fatigue" failures. This class of failure is met with in rails and is known as a failure from a "transverse fissure." Fig. 15 is a photograph of the top portion of a 100-lb. open-hearth rail which failed from this cause. The fissure

Fig. 20. Uniform, unstreaked structure in rail rolled from a reheated bloom. Etched with cupric chloride. $\times 10$.

the grains being surrounded by oxidized films, as in Figs. 12 and 13, which effectually prevent welding. "Overheated" steel has a coarse fracture and structure (Fig. 14) and, like "burnt" steel, is extremely brittle. Unlike "burnt" steel it can, however, easily be restored by suitable heat treatment. "Overheated" steel results from long annealing at a temperature below that of incipient fusion.

Reheating for a prolonged time even at a moderate temperature has a detrimental effect upon steel to be used for certain purposes. Treatment of this kind, say a long tempering just below the critical point of a steel containing pearlite, causes the pearlite to break up and the Fe_3C to form small globules in a ferrite matrix and eventually to coalesce into much larger particles. Thus we have large cementite islands surrounded by ferrite. This structure is the softest, weakest and most ductile which can be assumed by any steel containing pearlite,

can plainly be seen in the head of the rail. It shows the detailed fracture typical of "fatigue" fractures. Near the center of the smooth area can be seen the nucleus at which the fracture started. Once started it gradually progressed under the alternating stresses produced by passing trains until the surface was reached and the head completely broken.

It is, however, not with the progression of the fracture, but rather with its origin, that the writer would deal. A recent paper before the American Institute of Mining and Metallurgical Engineers presented convincing data that the origin of the transverse fissure—the nucleus—invariably occurred in brittle high-phosphorus areas in the rail. It also showed that rails in which the phosphorus was uniformly distributed rarely failed in this manner. A few photomicrographs illustrating the above are included herewith. They are all etched with Stead's cupric chloride reagent, which

Fig. 24. Good annealing. Etched with picric acid.

darkens the purer metal and leaves white the portions higher in dissolved impurities such as phosphorus.

Fig. 16 is a longitudinal section through the nucleus of a transverse fissure. The pointed projection is formed by a portion of the nucleus. This specimen has a distinct banded structure, showing a poor distribution of phosphorus, and it will be noted that the broadest white band—i.e., the most pronounced phosphorus segregation—occurs exactly at the nucleus. Fig. 17 was taken near the nucleus of another fissure. It shows the same banded structure and a longitudinal crack following closely the white high-phosphorus bands. Fig. 18 typifies the same structure found at the nucleus of a fatigue fracture which occurred in an airplane wrist-pin. Fig. 19 shows this same type of structure as found in poor tinplate.

As stated above, proper heat treatment will remove almost all danger from this source. The steel should be heated to a temperature well above A_c and held there for a long time to allow the proper diffusion of phosphorus to take place, after which the now coarse grain of the steel must be refined. In rail making it is merely necessary to reheat the bloom before rolling. The grain will be refined during subsequent rolling operations. Fig. 20 illustrates the structure of a rail so treated. Note the uniform phosphorus distribution and the absence of streaked structure.

At this point it would be well to mention a popular fallacy of which one frequently hears; namely, failure through "crystallization" caused by alternating stresses. This is not possible. A fatigue failure is the direct result of the gradual breaking down of the crystal grains.

ANNEALED STEEL CASTINGS

In a recent test of steel castings in which the author participated about forty heats of metal were made. Representative test pieces were taken throughout and specimens were subsequently cut from these for microscopic examination. After etching with picric acid they were classified as to annealing. Figs. 21 to 24 represent respectively bad, poor, fair and good annealing. Fig. 21 shows the well-known cast or Widmanstätten structure typical of all steel before heat-treatment. This structure is weak and brittle, especially under shock, and its elimination is the primary object in the annealing of steel castings. Under static or tensile tests these four classes of structure differ slightly in physical properties, but under shock great differences are readily made manifest. Analyses of these heats were approximately: carbon, 0.25; man-

ganese, 0.69; sulphur, 0.026; phosphorus, 0.019; silicon, 0.045. The results of the tensile tests averaged: yield point, 76,550; elongation, 29 per cent; reduction of area, 46.2 per cent. Under a Frémont drop test with a piece of given cross-section the bad, poor, fair and good annealing gave, respectively, resistance to impact of 2, 12, 15, 16.5 kilogram-meters, which agrees perfectly with what the microstructures would indicate. Fig. 21 shows a very pronounced Widmanstätten structure. Fig. 22 shows this less pronounced. Fig. 23 shows traces of the cast structure. In Fig. 24 it is altogether absent. The need for careful and thorough annealing is here clearly shown, especially in case the material is subject to shock or vibration. The test-bars used in the above were all attached to freight car castings and the differences in structure were readily traceable to variations in the annealing practice.

In concluding the author would say that he has hardly scratched the surface of his subject, but that the explanations and descriptions given are only those which are generally accepted by metallurgists. This paper and the preceding may, therefore, be of value to those who, although more or less interested in the subject, have not either the time or facilities for its study.

Niagara Falls, N. Y.

Newcastle Steel Works Expands

An expenditure of about £3,500,000 has been decided upon by the directors of the Broken Hill Proprietary Co. (Ltd.) of Australia for extensive additions to the present plant at the Newcastle Steel Works, where already 5,000 men are employed. The demands of the commonwealth for adequate supplies of iron and steel for newly established industries as well as increased orders from abroad brought about this decision. Two representatives of this company have been sent to the United States for the purpose of glean information relative to the cost of the required additional machinery, according to advices from Consul General Sammons, of Melbourne. All additions are planned to be completed in two years. Another blast furnace, making four in all, is to be erected, together with the added number of coke ovens required. A byproduct plant will be used in connection with the coke ovens. Other additions include a duplex steel plant, a continuous mill for the rolling of steel bars and billets, a duplication of the present rod mill, and a sulphuric-acid plant for the supply of acid in connection with the production of sulphate of ammonia and for galvanizing.

World's 1920-21 Sugar-Crop Estimates

THE world's sugar-crop estimate for 1920-21 is over 1,700,000 tons greater than the production of 1919-20. While definite advices have been received from many sources, some of the reports are only partial and are subject to adjustment, and it must be understood that in a great many instances there are still two or three months of growing weather that can materially affect the present outlook, says the *Weekly Statistical Trade Journal*. Under such conditions these crop estimates must be looked on as more of an indication than an estimate, but nevertheless they are quite valuable in determining what the prospects of supplies are for the next sugar year.

CANE CROPS EUROPEAN BEET CROP

As regards Cuba, while the usual inquiries have been sent to the factories, reports are coming in very slowly, due perhaps to the unsettled financial situation there. The centrals hesitate in giving any indication of their probable output until conditions improve. The Cuban weather during the growing season has been favorable in the western half of the island; the eastern half has been lacking somewhat in rainfall. Santa Clara Province was affected by a light rainfall. Increased planting has been reported in a number of sections. Ten or twelve new factories that are either complete or under construction may add something over last year's production. For the present the Cuban crop indication can be placed at 4,000,000 tons.

Santo Domingo and the British West Indies have all been affected by a more or less serious drought during the growing season and in some cases crops are reduced. The weather in Porto Rico has been irregular, but no material change is expected in the production. Formosa and Japan will show increased outputs. Dry weather prevailed in Natal and the Fiji Islands.

Preliminary figures issued several months ago, based on sowings, are not likely to be attained in the European beet crop. Many contributing circumstances have been the cause; partly irregular growing weather, lack of coal, transport materials, labor, etc. The figure for Germany, based on a yield per hectare much below a normal acreage, indicated on the area planted a crop of 1,300,000 tons, but even the low yield per hectare used by us will not be reached, and it is hardly likely that a crop in excess of 1,150,000 tons will be made in that country. Similar conditions obtain in Czechoslovakia; latest official advices from there state the crop would reach only 650,000 tons raw value. France is showing quite an improvement over the preceding crop and will probably have a production of 100,000 tons more than its last one. Spain also shows a material increase.

AMERICAN AND CANADIAN BEET CROPS

Regarding conditions in the United States, the output of the beet crop in Ohio is estimated at 45,000 tons, Michigan at 145,000, Colorado 250,000, Nebraska 75,000, Utah 140,000, Idaho 50,000, and California 151,000. In this last state the campaign is so nearly over that the figure given will be very close to the actual out-turn.

The above estimate is freely confirmed by the United States Government, which estimates the crop of beet roots as of Nov. 1 as 8,812,000 tons. Using an average

yield of the past three years (including last year's poor out-turn), gives a crop indication of 900,000 tons. This year's yield will exceed the three years' average materially, according to present prospects.

According to advices, prospects in Canada are very good, and with the material increase in sowings the indications are that a crop of at least 35,000 tons will be made.

The total indicated world production for 1920-21 of both cane and beet sugar is 17,085,500 tons, against the last campaign of 15,310,824 tons, an increase of 1,774,676 tons. The largest world's production on record was the 1913-14 campaign, when the production totaled 18,667,399 tons.

PRELIMINARY 1920-21 FIGURES

Preliminary estimates (in long tons) for the 1920-21 crop in the various sugar-producing countries of the world and the final estimates for the two previous crops follow:

Countries	1918 19 Tons	1919 20 Tons	1920 21 Tons
United States:

Refractories for Electric Furnace¹

A description of the Properties of Refractory Brick and of the Raw Materials Employed in Their Manufacture, With a Review of the Many Factors Involved in the Efficient Use of Refractories in General

BY R. M. HOWE†

BEFORE discussing the subject from a theoretical or practical standpoint the writer wishes to present certain data to be used as a foundation. These data have been gathered from both private and public sources, and acknowledgement is hereby made of the splendid co-operation of individuals interested in this field.

PHYSICAL AND CHEMICAL DATA RAW MATERIALS

There are nine raw materials which are most commonly used in or which are being most seriously considered for use in the manufacture of electric-furnace linings. They are fireclay, silica (or ganister), magnesite, dolomite, chrome, bauxite (and diaspor), zirconite, carborundum and alundum. The last two are mentioned by their trade names, as considerable data are given as applying to these products. Strictly speaking, they are not raw materials, but can be classed as such most advantageously and used to represent this general type of material.

The ranges of analyses given in the accompanying table are believed to be typical of the materials used for refractory purposes.

A discussion of the influences of different impurities must be omitted, as this would be the subject of a paper in itself.

ANALYSES OF REFRACTORY RAW MATERIALS

The refractory bricks or shapes made therefrom have similar analyses. In many cases the difference in composition between the raw material and the finished product is simply due to the removal of carbon dioxide, water or organic matter, but in a few cases it is the

result of the addition of a binder, as for example the lime in silica brick.

PROPERTIES OF REFRACTORY BRICK

Fusion Point.—The fusion points of a number of refractory brick were published by Kanolt¹ in 1912, and as they agree closely with those secured by the writer, Kanolt's results are given herewith. That of zirconia brick has been determined by several investigators, but the results of Arnold² and Ruff³ show the best agreement, being 2,600 deg. C. and 2,563 ± 10 deg. C., respectively. Fused bauxite, or alundum, fuses at 2,050 deg. C.⁴ Silicon carbide, or carborundum, does not fuse but decomposes at about 2,240 ± 5 deg. C.

FUSION POINTS OF REFRACTORY BRICK

	Deg. C.
Fireclay.....	1615 to 1715 ¹
Silica.....	1700 to 1705 ¹
Magnesia....	2165 ¹
Chrome.....	2050 ¹
Bauxite.....	1565 to 1785 ¹
Zirconia.....	2563 ± 10 ²
Carborundum, decomposes at	2240 ± 5 ³
Alundum.....	2050 ⁴

When the fusion point of refractory material is determined, the results actually show the temperature at which a small piece of the material softens under its own weight. When the influence of pressure, as well as that of high temperatures, is taken into consideration far different results obtain.⁵ Fireclay brick begin to compress slowly at about 1,350 deg. C. when a pressure of 50 lb. per sq.in. is applied. Zirconia brick "squatted" at 1,420 deg. C. and 1,600 deg. C. under pressures of 75 and 25 lb. per sq.in. respectively. Magnesia,

BEHAVIOR OF REFRACTORY BRICK WHEN HEATED
UNDER PRESSURE OF 50 LB. PER SQUARE INCH

Kinds of Brick	Investigator	Behavior
Fireclay	Bleiningger and Brown	Softens at about 1,550 deg. C.
Silica	Brown, Le Chatelier	rigid at 1,500 deg. C., but probably shears at about 1,600-1,650 deg. C.
Magnesia	Brown, Mellor and Emory	Shears at 1,410-1,555 deg. C.
Chrome	Brown, Mellor and Emory	Shears at 1,400-1,450 deg. C.
Zirconia	Estimated from Mellor and Emory	"Squats" at about 1,510 deg. C.
Bauxite	W. F. Rochow	Softens at about 1,350 deg. C.
Carborundum	B. C. Landberger	No signs of failure at 1,650 deg. C. the furnace limit

chrome and silica brick usually show slight signs of softening under pressure and then suddenly shear. Load tests on bauxite brick showed compressions of from 1.96 to 6.35 per cent¹ under a pressure of 25 lb. per sq.in. at 1,350 deg. C. after one and one-half hours.

Carborundum brick do not fail at 1,650 deg. C. under a pressure of 50 lb. per sq.in. The accompanying table indicates what may be expected of different kinds of refractory brick when heated under a pressure of 50 lb. per sq.in.

SPECIFIC GRAVITY OF REFRACTORY BRICK

The following data, gathered from different sources, illustrate rather clearly how the weight of an installation depends upon the type of bricks used.

Material	Specific Gravity
Fireclay	2 65 2 75
Silica	2 29 2 44
Magnesia	3 44 3 60
Chrome	3 90 4 00
Carborundu	3 12 3 20
Bauxite ¹⁰	3 15 3 25
Alundum ¹¹	3 90 4 00
Zirconia ¹²	5 0

The higher values for zirconia, bauxite, chrome, magnesia and fireclay brick generally indicate harder burning, while the specific gravity of silica brick decreases with the intensity of the burn.

ELECTRICAL RESISTIVITY OF REFRACTORY BRICK

It is natural that interest in the electrical resistivity of refractories has increased with the more general application of the electric furnace, yet very little information on the subject is available. Stansfield, MacLeod, and McMahon¹¹ have compared the resistivity at high temperatures of silica, Austrian magnesia and chrome brick made in America, and firebrick from Caledonia. Certain data regarding the resistivity of electric furnace products are given in trade catalogs, but otherwise there is very little information available.

ELECTRICAL RESISTIVITY IN OHMS PER C.C.

Temp. Deg. C.	Magnesia Brick ¹⁴	Chrome Brick ¹⁴	Silica Brick ¹⁴	Fire- brick ¹⁴	Carbor- undum ¹⁵	Alundum ¹⁶
528				21,000	14 6	130
600				17,000	10 9	16 (730 deg. C.)
700				13,000	7 8	
800		2,800		9,000	5 4	5 3 (892 deg. C.)

SPECIFIC HEATS OF REFRACTORY BRICKS

Aside from the data given by Heyn¹² for silica and magnesia brick, and that given by Mellor¹³ for fireclay

SPECIFIC HEATS OF REFRACTORY MATERIALS

Material	At 100 Deg. C.	At 1,000 Deg. C.
Firebrick ¹⁸	0 199	0 253
Silica ¹⁷	0 219	0 298
Magnesia ¹⁷	0 234	0 324
Alundum ¹⁸	0 198	
Carborundum	0 186 (31,985 deg.)	

brick, little is known regarding this constant. Other investigators¹⁹ have simply reported determination over

a narrow and low temperature range and have apparently disregarded the fact that specific heat increases with the temperature.

THERMAL CONDUCTIVITY OF REFRACTORY BRICK

The thermal conductivity of refractory brick has been determined several times, and in a number of instances remarkable checks have been secured. In nearly every investigation, however, there has been one marked deviation which has been due to the material used. For example, Wologdine²⁰ used a silica brick sample which was not typical of American manufacture and noted a conductivity lower than that of fireclay. In other cases concordant results have been secured except with magnesia brick, a fact which leads one to believe that the samples were not typical of the product used in commercial furnaces for withstanding the action of metal, slag and high temperatures. When these apparent discrepancies are eliminated, the results show rather close agreement, as may be seen in the accompanying table of selected data.

THERMAL CONDUCTIVITY OF REFRACTORY BRICK AT 1,000 DEG. C. IN COLONIES PER CENTIMETER CUBE PER SECOND PER DEG. C.

Observer	Fireclay	Silica	Magnesia	Chrome	Carborundum
Dudley.....	0 0044	0.0042			
Wologdine.....	0 0042		0.0071	0.0057	0.0231
Dougill, Hodsman and Cobb.....	0 0040	0 0046	0 0085		
Goerens and Gillis.....			0 0080		
Average.....	0 0039	0 0044	0.0079	0.0057	0.0231

Zirconia²¹ brick are said to have a very low thermal conductivity. That of silica brick has been observed to increase greatly at 1,050 to 1,100 deg. C.²²

RESISTANCE TO TEMPERATURE CHANGES

Refractory brick and shapes made from fireclay and electric-furnace products are only slightly affected by sudden changes in temperature. Silica, magnesia and chrome brick must be heated very slowly, especially at low temperatures, if spalling is avoided. When once heated, however, any of these bricks will withstand

Material	Fusion Point Deg. C.	Point of Failure Under 50 lb. per sq. in. Load, Deg. C.	Thermal Conductivity at 1,000 Deg. C.	Specific Heat at 100 Deg. C.	Resistance to Spalling

considerable variation in temperature if the change is not too sudden. The more important data regarding the thermal properties of the various refractories have been grouped into tabular form for convenience of reference and comparison. In many instances specific data are lacking, so the writer has taken the liberty of supplying relative data or comparative notes to aid in the formulation of conclusions. The specific data represent the average results obtained.

³⁰Trade catalogs of the manufacturers.

There is little doubt that the use of fireclay brick for metallurgical purposes is advisable wherever they give satisfaction. They are inexpensive, easy to install, and require less care in handling than any other refractory material. However, it is realized that there are serious limitations to the application of fireclay brick in the electric-furnace industry because of the extremely high temperatures involved. Consequently, it is necessary to secure the most refractory firebrick available for use in the hotter zones, and even then the furnace temperature should not exceed 1,650 deg. C. for any length of time. Since this temperature is very close to the fusion points of the more refractory fireclays, satisfactory service is secured by applying certain precautions which tend to increase the life of any refractory.

PRECAUTIONS AIMING TO INCREASE THE LIFE OF REFRACTORIES

Insulation of any kind should be carefully avoided when fireclay brick are used at their limiting temperatures, for when the heat which is naturally carried away accumulates on the inner hotter surface failure invariably results. Care must be exercised in preventing the accumulation of plant dust on the furnace roof, for it acts as an insulator and sometimes causes failure. It is also advisable to make the ratio between the heating surface and the radiating surface as small as possible in order to secure additional service from the lining. Undoubtedly the use of water cooling plates would be advantageous, as has been demonstrated in the hotter zones of a blast furnace. A refractory block should never be heated from more than one surface, especially when under pressure; the results of this condition are shown by the load tests.

These rules apply to any kind of refractory material.

USE OF SILICA BRICK

When fireclay brick do not give satisfactory service in roofs silica brick are usually installed. They have fusion points which are practically the same as those of the more refractory fireclay brick, but possess other characteristics which favor longer service. They must, however, be heated very slowly, especially at the lower temperatures, because of their tendency to spall. When this precaution is taken and a temperature of over 1,000 deg. C. is maintained, a silica brick roof should give extended service.

When the roof is heated rapidly strains develop, but are often unnoticed because the expansion of the brickwork holds the brick and pieces in place. Upon cooling, however, the brickwork contracts and reduces the pressure on the different parts of the roof, thus allowing the loosened portions to fall into the hearth. It is believed that if the pressure could be maintained during a cooling period spalling would be less pronounced. Upon heating up again it would be necessary to release gradually the pressure to allow for the expansion of the brick, in order to prevent their being crushed.

It has been the writer's experience that the smaller silica shapes spall less readily than the heavier blocks, due probably to the great expansion strains developed in the latter during the heating periods. This fact would favor the use of small standard sizes rather than the larger special shapes.

There are two characteristics possessed by silica brick which are evidently associated with their satisfactory service in roofs. They have a relatively high thermal conductivity, which helps cool the brickwork, and they

are rigid under a pressure of 50 lb. per sq.in. at temperatures within 100 deg. C. of their fusion points. It is believed that these two facts, coupled with the high viscosity of silica, explain why brick of this type can be used at temperatures very close to their actual melting points. Care should therefore be exercised in furnace design and construction to develop the thermal conductivity of the walls to the maximum. Brick made from various sized angular fragments and burned so as to convert a large proportion of the quartzite to tridymite and cristobolite (indicated by a specific gravity of 2.29 to 2.38) usually have the greater strength at high temperatures.

The use of fused silica brick has not been overlooked, and it is doubtful if they would spall. Their cost, however, would hardly be justified, as more refractory electric-furnace products could be prepared at a slightly greater expense.

USE OF MAGNESITE BRICK

Magnesia brick are favored with a high fusion point, thermal conductivity and resistance to the corrosive action of slag and metal. Because of this fact the brick and grains are used extensively in the hearths and bottoms of basic furnaces. They have less desirable characteristics of being subject to spalling and to the chemical action of certain substances. Extreme care must therefore be exercised in the selection, treatment, installation and use of this material.

The magnesite after being burned should contain from 4.0 to 8.5 per cent of ferric oxide, as this impurity facilitates "sintering." When this amount of iron oxide is present and the specific gravity is from 3.44 to 3.60, the product is sure to be well burned, resistant to slaking and will undergo little or no contraction after being installed. Either the grains or the brick made therefrom may be stored indefinitely if protected from water. These characteristics will be affected by the lime content, which, as is generally conceded, should be low. Investigations reported elsewhere have led to the following conclusion regarding the influence of this oxide.

"The magnesite that was lower in lime showed less tendency to slake and higher refractoriness, as well as greater resistance to attack by firebrick and silica brick, and to the action of the corrosive mixture."

Dense hard burned magnesia brick have a thermal conductivity higher than that of silica brick and permit only slight slag penetration.

They should be laid dry in order to prevent any possible action with water and should never be exposed to the action of steam," which causes them to disintegrate.

They are attacked by carbon at 1,700 deg. C." according to the following reversible equation:

As this action proceeds, a gray or black deposit consisting of an intimate mixture of magnesia and carbon is deposited in the cooler zones. Both silicon and phosphorus also attack magnesite when they are present in the melt, that high in lime being most easily affected.

When the grains are used in the hearth they should be sintered into place in $\frac{1}{2}$ - to 1-in. layers over a foundation of magnesia brick, using a small amount of

²² McDowell and Howe, *Am. Inst. Min. Eng. Bull.* 146, p. 309 (1919). The corrosive mixt. contained phosphorus, silica and ferric oxide.

²³ R. H. Youngman, *J. Am. Chem. Soc.*, vol. 3, p. 217 (1920).

²⁴ P. Watts, *Trans. Am. Electrochem. Soc.*, vol. 11, p. 279 (1907).

²⁵ Goodwin and Maib, *Ibid.*, vol. 9, p. 89 (1906). R. E. Slade, *J. Chem. Soc.*, vol. 93, p. 327 (1908). P. Labean, *Compt. rend.*, vol. 144, p. 799 (1907).

slag as a binder. This practice should result in the formation of the densest structure, one which would be less easily scoured or loosened in patches.

Dolomite is rarely, if ever, used in the manufacture of brick at the present time because of the difficulty encountered in preventing the lime from slaking. Several years ago such brick were made at different European steel plants, but as it was necessary to use them immediately in order to prevent their disintegration they were gradually replaced by magnesite brick.

The use of dolomite in patching and, in a few cases, for building entire bottoms has continued to the present day, probably because of its low initial cost as compared with that of magnesite. Dolomites highest in magnesite and containing about 4 per cent of iron oxide and alumina apparently have the most desirable characteristics; when over 4 per cent is present, especially when accompanied by more than 3 or 4 per cent of silica, the product is less refractory.²²

The writer has compared burned dolomites with "treated" dolomites and dead-burned magnesites and drawn the following conclusions:

The magnesites are more resistant to slaking than the dolomites or dolomite preparations, also to the action of the corrosive mixture and that of fireclay and silica. One of the treated dolomites has a slaking tendency so low as to group it with the magnesites; in its resistance to corrosion it compares more closely with the untreated calcined dolomite high in impurities.

The materials highest in impurities and lowest in lime were most resistant to slaking.²³

USE OF CHROME, ZIRCONIA, BAUXITE AND OTHER SPECIAL BRICK

Chrome brick have certain desirable characteristics, but are rarely used in electric furnaces. They are favored by a high thermal conductivity, fusion point and resistance to slagging action. On the other hand, they are difficult to bond, the chromic oxide may be reduced to chromium, and this may contaminate the metal being melted.

The use of a layer of chrome brick or of chrome ore has proved to be a very satisfactory method of separating silica and magnesite brick in order to prevent their interaction at high temperatures. It is possible that chrome, because of its insolubility, might be utilized at the slag line either by itself or in conjunction with magnesite. The successful use of chrome might greatly increase the resistance of the lining to the action of the slag, which dissolves the magnesite or dolomite so rapidly.

As far as the writer is aware few zirconia brick, if any, are being used in electric furnaces, although several investigators believe that their use will solve many problems. These opinions are based upon the high fusion point of the pure material, the low conductivity of the brick, and their marked resistance to the solvent action of certain fluxes.

There are numerous commercial disadvantages, however, which must be overcome before the full refractory value of zirconite is developed. The mineral is often badly contaminated with iron oxide and as a result its fusion point is seriously lowered. It also undergoes considerable shrinkage at high temperatures and must therefore be given a severe heat treatment before

installation, in order to prevent shrinkage in service. It is evident that the raw material used in the brick tested by Mellor²⁴ was not properly selected or else it had not been sufficiently burned. Otherwise brick fusing at about 2,474 deg. C. would not have "squatted" at 1,420 deg. C. under a pressure of 75 lb. per sq. in.

Bearing in mind that the influence of impurities and of the incomplete removal of shrinkage will be accelerated by the low thermal conductivity of the brick, it is evident that three things must be accomplished before the full value of zirconite as an electric furnace refractory is realized:

1. Raw material of the necessary purity must be available, either by proper sorting or purification.
2. It must be bonded into a mechanically strong brick.
3. This brick should undergo little shrinkage after being installed.

Very little is published regarding the use of zirconia in binding up furnace bottoms. When its high fusion point and insolubility is considered, this possibility is not remote.

Bauxite brick have characteristics very much the same as those made from zirconite, a fact which is not surprising because of the similarity in behavior of the dominating oxides found in each. In order to secure the full value of bauxite as an electric-furnace refractory it is therefore necessary to subject the brick to an intense heat treatment in order to completely remove the shrinkage. Bauxite brick do not possess the advantage of having a high thermal conductivity.

Carborundum and alundum offer good possibilities for service in roofs, as they have all of the assets of silica brick, with the additional advantage to a low tendency to spall. Their fusion points are high, as is the thermal conductivity. Their tendency to shrink is naturally low, and they can support a heavy load at high temperatures. The writer is unable to state to what extent they are affected by furnace gases or slag. In a few cases oxidation of the silicon carbide to silica, resulting in the weakening of the brick structure, has been reported. It is probable that the practice of insulating bricks of this type could be practiced with greater safety than with other types, because of their higher fusion points and low shrinkage.

CONCLUSIONS

In conclusion, the writer wishes to emphasize certain factors concerning the service secured from refractory brick. They should be protected from rain while being stored in order to prevent the weakening of their structure. They should be laid up with a material similar to the brick themselves, or one which will not corrode or flux them, using as small a joint as possible. The furnace should be constructed so that heat will be conducted away from the hotter portions. The ratio of heating to cooling area should be made as low as possible. Refractory brick or shapes should be heated from one side only in order to keep the heating surface low and in order to avoid the effect of pressure at high temperatures. Insulation lowers the margin of safety and should therefore be avoided, even to the extent of allowing dust to accumulate on the roof. When the furnace is being heated this should be done gradually, especially where magnesite and silica brick are involved. When the furnace is being cooled it should be remembered that cold blasts produce or accelerate spalling.

Adsorption by Silica Gel*—II

Adsorption Efficiencies on Ethyl Ether, Acetone, Benzene, Water and Petroleum Ether Vapors—Experimental Results—Dehydration of Air at Various Saturations—Solvent Recovery†

By E. B. MILLER

CONSIDERABLE losses of valuable solvents such as ether, acetone, alcohol, benzene, etc., occur in a variety of industrial processes. In the recovery of such solvents silica gel will probably find some of its most important applications. The general principles already discussed apply in this field and we can predict approximately the adsorptive power of the gel for the vapor of a particular solvent before determining it experimentally. These general principles have already been illustrated in some detail by experimental data on sulphur dioxide, and it will not be necessary to go into the same detail hereafter.

For the recovery of solvents after they have been adsorbed by the gel the most satisfactory method,

FIG. 6. ADSORPTION EFFICIENCY ON ETHER VAPOR

applicable in nearly all cases, consists in heating the gel to the proper temperature and sending steam directly through it. For the volatile solvents here considered 105 deg. C. is sufficient to bring about rapid distillation from the gel. This method is particularly adapted to the recovery of substances which, like ether, benzene, etc., are but slightly soluble in water and do not react chemically with it.

Steam displacement was used in the laboratory experiments described below. In carrying out an experiment the tube containing 100 g. of gel with its adsorbed material is connected on one side with a source of steam and on the other with a condenser and receiver, the latter being so constructed that its contents may be drawn off and weighed. When all connections are made the gel is heated to about 105 deg. C. by immersion in an oil bath. During heating some of the adsorbed material generally distills out. When the desired temperature is reached steam is admitted to the gel and the mixed vapors are condensed and collected in the receiver.

In reference to the percentage recoveries of the

various solvents as shown in the following pages it should be pointed out that, working on such a small scale, the experimental errors are relatively large. No very special effort was made to eliminate losses in handling and weighing the distillates.

ETHYL ETHER

Fig. 6 gives the results of two typical experiments on the adsorption of ether vapor at 25 deg. C.

The desired mixture of ether vapor and air is obtained by saturating a metered volume of air by bubbling it successively through several bottles of pure ether kept at a constant temperature. The resulting mixture may, if desired, be diluted by further admixture with air. The weight of ether carried by the air is determined by absorbing it completely from a known volume in a weighed portion of silica gel and noting the increase in weight. From the weight of ether in a known volume the volume per cent is calculated on the assumption that the gas laws hold for ether vapor, which is of course only approximately correct.

An examination of the curves show that, using a 1.00

FIG. 7. ADSORPTION EFFICIENCY ON ACETONE VAPOR

per cent mixture of ether vapor and air, the gel adsorbs at 25 deg. C. an amount of ether corresponding to 14.4 per cent of its own weight; and, using a 3.08 per

losses in handling and weighing. We carried out the next experiment using colder water in the condenser in order to minimize the loss by evaporation through the vent in the receiver.

FIG. 9. ADSORPTION EFFICIENCY ON WATER VAPOR

The vent in experiment 2 adsorbed 0.095 g. of ether.

ACETONE

Fig. 7 shows the results of several experiments on the adsorption of acetone vapor at 25 deg. C. from mixtures with air ranging in concentration between 1.18 and 8.9 per cent acetone vapor by volume.

The mixtures with air and analyses of same were made in a manner similar to that already described for ether. The data given on the curve sheet are self-explanatory.

We give here the results of three experiments in the recovery of adsorbed acetone.

Experiment 1. A tube containing 100 g. of gel with 33.8 g. of adsorbed acetone was connected with a source of steam, a condenser and a receiver as already de-

scribed. During the heating some acetone was distilled out and condensed in the receiver, but the amount was not determined separately. When the temperature reached 105 deg. C. steam preheated to 112 deg. C. was passed through the gel for a period of eighty minutes; 94.44 c.c. of condensate was obtained which had a density of 0.94094. This corresponds to 33.77 g. of acetone, or 100 per cent recovery.

Experiment 2. One hundred grams of gel containing 33.3 g. of adsorbed acetone. Temperature of condenser 20 deg. C. Temperature of receiver 0 deg. C. Receiver vented to air.

During heating to 107 deg. C. 8.0485 g. of acetone distilled over. Steam was then passed for twenty minutes, giving a distillate of 16.9726 g., having a density of 0.81529 at 25 deg. C. This corresponds to 15.36 g. of acetone and 1.6126 g. of water.

Further steaming for thirty minutes gave a distillate of 26.69 g., having a density of 0.9770 at 25 deg. C. This corresponds to 3.87 g. acetone and 22.82 g. water.

Acetone recovered was 27.28 g., or 82 per cent of the total.

Experiment 3. One hundred grams of gel containing

FIG. 9A. DRYING POWER OF SILICA GEL $P/P_o = 1$

33 g. of adsorbed acetone. Temperature of condenser, 0 deg. C. Temperature of receiver, 0 deg. C.

Acetone to the amount of 6.062 g. distilled over during heating to 107 deg. C. Steaming for ten minutes gave a distillate of 34.47 g., having a density of 0.8654 at 25 deg. C. This corresponds to 24.8184 g. of acetone and 9.6516 g. of water. Further steaming gave no liquid acetone.

Acetone recovered, 30.8827 g., or 93.5 per cent of the total. During distillation the receiver was vented through a column of gel. Only a negligible increase in weight occurred.

BENZENE (BENZOL)

Fig. 8 gives the results of some adsorption experi-

FIG. 9B. DRYING POWER OF SILICA GEL $P/P_o = 0.53$

FIG. 9C. DRYING POWER OF SILICA GEL $P/P_0 = 0.287$

ments on benzene. The curves follow very closely the corresponding curves for acetone. Concentrations were determined in the manner already described.

Recovery. Two experiments are given, differing with respect to the temperature of the condenser and the amounts of adsorbed benzene present.

WATER

We have seen that silica gel, even after activation, always contains some water. The water content varies between 5 and 7 per cent by weight, depending upon the temperature and time of activation. By prolonged heating in an air stream the water content may be reduced

FIG. 10. ADSORPTION EFFICIENCY OF WATER VAPOR

below 5 per cent, but gel with 5 to 7 per cent gives better adsorption. For the sake of clearness in presentation we distinguish between this residual water, always present, and adsorbed water.

Fig. 9 shows the adsorption of water at 30 deg. C. from air saturated at 30 deg. C., using gel with an

initial water content of 7 per cent. The air was passed through the gel at the rate of 50 c.c. per minute per gram of gel, thence over weighed phosphorus pentoxide. The increase in weight of the latter gave the water content of the air dried by the gel. For the first two hours the amount of water in the air as it left the gel tube remained constant at 0.3 mg. per liter, which corresponded to 99 per cent efficiency. In other words, the relative humidity of the air dried by gel was 1 per cent. At the end of two and a half hours the efficiency was still 98 per cent and the gel had adsorbed 21 per cent of its own weight of water. Adsorption continued till the gel had taken up an amount of water corresponding to 25.7 per cent of its own weight, which is here called the saturation value.

Figs. 9-A, 9-B, 9-C show the drying power of silica gel at 30 deg. C. using air with varying amounts of moisture ranging from 100 per cent to 26.7 per cent relative humidity at 30 deg. C.

Fig. 10 shows the adsorption of water at 20 deg. C. from air saturated at 20 deg. C., using a rate of 100 c.c.

FIG. 11. REMOVAL OF WATER FROM SILICA GEL.

per minute per gram of gel. Here again we have 99 per cent efficiency for 105 minutes, at which point the gel had taken up 18.5 per cent of its own weight of water. Saturation value was 28 per cent.

Fig. 11 gives in graphic form a summary of a large number of experiments on the removal of adsorbed water by air displacement. Experiments have shown that at temperatures from 125 to 200 deg. C. the rate of removal is dependent mainly on the volume of air used, and increases only slightly with increase in temperature. We accordingly do not include here work done above 125 deg. C.

Curves I, II, III and IV show the percentages of adsorbed water removed against time for rates of air flow ranging from 5 c.c. to 50 c.c. of air per minute per gram of gel. An examination of Curves III and IV

indicates that the adsorbed water is removed about as rapidly with air at 30 c.c. per minute as with 50 c.c. per minute.

Curves V and VI show the same experimental results in which the rate of air flow is plotted against the time necessary to remove 95 per cent of the adsorbed water at 125 deg. C. and 105 deg. C. respectively. An inspection of these two curves will make clear that at these temperatures little will be gained by increasing the rate much above 20 or 30 c.c. per min. per g. of gel.

GASOLINE

The results of two laboratory experiments at 25 deg. C. are given in Fig. 12. The mixtures of air and gasoline were made in the usual way. The decrease in con-

FIG. 12. ADSORPTION EFFICIENCY OF GASOLINE

centration of gasoline vapor during each experiment was, of course, due to the removal of the more volatile constituents from the gasoline used to saturate the air.

In order to make the tests on recovery of gasoline as rigorous as possible we used in the experiments here described not ordinary gasoline, but petroleum ether, which contains only the lower boiling constituents of gasoline. The hydrocarbon vapors were introduced into the gel in the usual way, viz., by bubbling air repeatedly through petroleum ether at 23 to 25 deg. C. and leading the air thus saturated over the gel kept at the same temperature. For recovery the same procedure was followed as has already been described for other solvents.

Legal Notes

BY WELLINGTON GUSTIN

Liability for Loss in Shipment Due to Leakage

The Supreme Judicial Court of Massachusetts has affirmed the judgments against the Florida Cotton Oil Co. in its suits against the Clyde S. S. Co. and the Maine Coast Co. The defendants were sued as common carriers to recover for the loss of 458 gal. of cottonseed oil, being part of a shipment of 100 bbl. of the oil.

The Florida company delivered to the Clyde S. S. Co. at Jacksonville, Fla., 100 bbl. of oil to be transported under a bill of lading to Machiasport, Me., for the Machiasport Packing Co. The oil arrived on Sept. 10 in Boston, where the barrels were transferred on the day of arrival to the Maine company, which forwarded the oil in two shipments, one on Sept. 12 and the other on Sept. 16, to Machiasport, where it was found there had been a loss of 458 gal. The oil had been received at Jacksonville in barrels which "were new six-hoop, white oak, hand-made barrels well coopered, made of well-seasoned timber and were tested" thoroughly before being used.

The Clyde company defended on the ground that when it delivered the oil to the Maine company no leakage had occurred, and under the eighth clause of the bill of lading, that "no carrier shall be liable for loss or damage not occurring on its portion of the route, nor after said property is ready for delivery to consignee, . . . it is not responsible if any loss thereafter occurred." It also contended that under the exemption clauses, that no carrier shall be liable for damages caused by leakage, chafing or loss in weight, it is not liable, because the Florida company failed to offer any negligence from which negligence can be found.

RULE OF LAW WELL SETTLED

The court cited the rule laid down in another case, as follows:

"The law is well settled in this commonwealth and in most of the United States that a corporation established for the transportation of goods for hire between certain points and receiving goods directed to a more distant place is not responsible beyond the end of its own line, as a common carrier, but only as a forwarder, unless it makes a positive agreement extending its liability."

The Supreme Court said that while the shipment was an interstate shipment and under the act of Congress commonly called the Carmack amendment the initial carrier, where the shipment is by rail, or partly by rail and partly by water, is made liable for a loss upon the line of a connecting carrier even if the property had been received under a bill of lading restricting the initial carrier's liability to loss upon its own line, the transportation in the present case having been entirely by water, the initial carrier is not liable for loss on the line of a connecting carrier, except under common law rules.

The first and second provisions of the bill of lading agreed that negligence should not be presumed against the carrier, as is presumed under the common law; and further "no carrier or party in possession of all or

any of the property herein described shall be liable for any loss thereof or damages thereto by causes beyond its control . . . or by leakage, breakage, chafing, loss in weight, decay, vermin, changes in weather, heat loss or wet."

But the court held that though just and reasonable conditions may be imposed limiting the common law liability of a carrier, he cannot be relieved when the goods are lost or destroyed during carriage through his own negligence or the negligence of his servants or agents, though the contract of shipment may exonerate him in its terms. And a provision exempting the carrier from loss by leakage is reasonable.

The Florida company introduced no evidence other than leakage as the cause of the loss. Now the responsibility of the terminal carrier is the same as that of the initial carrier. The Maine company took the oil under the bill of lading issued by the initial carrier, and any valid limitation therein inured to its own benefit. Since the provision against liability by leakage was valid, the Florida company to recover must prove that the leakage was caused by the active negligence of the carrier. This it failed to do, and judgment was affirmed against it.

Logan Patent for Creosoting Apparatus Held Not Infringed

The Logan patent, No. 836,592, for creosoting apparatus as limited by the prior art, has been held by the United States Circuit Court of Appeals, Ninth Circuit, not infringed in the suit brought by Logan and the National Lumber & Creosoting Co. against J. H. Baxter and W. H. Jordan.

The object of the Logan invention is to provide means for treating with preserving fluids the butt ends of poles used for telephone, telegraph, electric lights, etc., by what is known as the hot and cold process. The apparatus presents three vats, into one of which the poles to be treated are placed on end upon bars which are arranged between heating coils. Above the treating vat is a reservoir tank, from which creosote or other fluid runs by gravity through a pipe and a valve. Below the treating vat is a relief tank, into which hot fluid from the treating tank is suddenly discharged by gravity through a large pipe. In operation, as soon as the hot creosote is discharged, cold creosote is let immediately into the treating vat to complete the treatment.

The status of the prior art runs back to a patent No. 391 issued to August Gotthieff in 1837. Various patents cover every element of the Logan claim, says the court, except means for the sudden removal of hot fluid from the treating vat.

The apparatus of Baxter and Jordan is operated by heating the preserving fluid in the treating vat after the poles are inserted, afterward withdrawing the heat, the fluid remaining and being allowed to cool, the poles remaining in the single bath twenty-four hours. In view of the prior art the court says the scope of the Logan patent is limited to the apparatus described in claim 2 of his patent, that being a treating vat fitted with a small pipe to introduce fluid from a supply tank, and a large pipe to permit sudden and immediate discharge by gravity of the hot fluid into another tank, so that cold fluid may be immediately introduced into the treating tank for completing the process of impregnation. The apparatus of Baxter and Jordan has no means by which creosote may be immediately withdrawn from the treating vat into a relief tank. Their cylin-

der placed below the treating vat has no such office, and without adjustment it could not be so used. These differences, the court said, avoided infringement.

A decree for Baxter and Jordan was affirmed.

Chemical Company Liable for Deaths of Boys • Bathing in Poisonous Abandoned Pool

The responsibility of a manufacturing plant for its vacated premises is the controversy involved in an action of Van Britt against the United Zinc & Chemical Co., decided in the United States Circuit Court of Appeals of the Eighth Circuit.

The facts involved show the chemical company owned and operated at Iola, Kan., a plant at which it manufactured sulphuric acid and zinc spelter. In 1910 it tore down the buildings on the premises, moved the machinery and wreckage away, and since then has not occupied or used the land for any purpose. There was a basement containing acid tanks with lead pipes in and out under what was known as the tower building, and when it was torn down chemical refuse was thrown into the open basement. As the tanks and pipes were taken out some sulphuric acid got into the basement. Other chemical refuse was left about on the surface, and the old basement later became a pool of clear water from surface drainage, strongly impregnated with sulphuric acid and zinc sulphate. The vacant property covers about twenty acres and is located on the outskirts of the town.

In 1916 Van Britt and family were traveling overland and camped for a few days not far from the pool. His two boys, eight and eleven years old, in passing it one afternoon, responded to boyish impulses and went in bathing. A short time after going in the younger was dead in the pool, the older was taken out, removed to a hospital and died two days later "from swelling of the bronchial tubes, and gastro-intestinal irritation, irritation of the stomach and bowels, which produced an inflammation of the bowels and stomach." He had colicky pains, vomiting and gasping for breath. Both deaths were attributed by experts to the poisonous chemicals in the water which had been taken internally. The water, when so taken, caused an immediate burning in the throat and choking; and applied outwardly it caused itching and slight sense of burning.

Van Britt brought action for damages against the chemical company, charging that it carelessly and negligently left the pool of poisonous water open and exposed, and without inclosure, barrier, danger signals or warnings of any kind about it, that it maintained the poisonous pool and failed to fill it up.

The general principle of law is that no one may use his property to the injury of another. The court says there is a conflict in the decisions as to the extent and under what conditions this rule may be carried against one as a basis for liability on account of injuries to children resulting from dangerous attractions which he places upon or suffers to continue on his premises. The application is made more freely where the thing complained of is put to no useful, ornamental or other purpose of enjoyment.

Where the inclosure around a tract of land formerly used, for manufacturing purposes had fallen away, so that the public were free to go at will and had made footpaths across it, if a pool of water impregnated with poisonous chemicals was attractive to boyish instincts and impulses as a place to go in bathing, and boys yielding to such impulses were killed by the poisons, it was immaterial whether the boys saw or could see

the pool before they entered upon the tract, said the court. The law does not class children of tender years with idlers, licensees or trespassers upon the property.

Further it was said that where a manufacturing plant had been abandoned and dismantled, and the inclosure had fallen away, so that the public crossed the premises at will, the law imputed knowledge and consent to such use to the owner. And where boys, who responded to the desire to go bathing, were killed by the poisonous chemicals, the owner's liability and amount of damage were questions of fact for the jury.

In another case the court said: "The occupant or owner of premises who invites, either expressly or impliedly, others to come upon them, owes to them the duty of using reasonable and ordinary diligence to the end that they be not necessarily or unreasonably exposed to danger; and an implied invitation to another to enter upon or occupy premises arises from the conduct of the parties, and from the owner's knowledge, actual or imputed, that the general use of his premises has given rise to the belief on the part of the users thereof that he consents thereto."

Judgment against the chemical company for the wrongful deaths was affirmed in the Court of Appeals.

Bills of Lading Construed in Light of Contemplated Adventure

In a suit by W. R. Grace & Co. against Frank Waterhouse & Co. to recover damages for injury to goods caused by the delay in transportation thereof from Hongkong to San Francisco, the United States Circuit Court of Appeals has affirmed the lower court's judgment in dismissing the suit, and holding that bills of lading are to be construed in the light of the nature and details of the adventure which was contemplated by the parties.

The merchandise involved was carried by the steamship from Hongkong to Seattle and there discharged and placed in a warehouse. It was delayed there two months by a stevedores' strike, and when forwarded by the Waterhouse company to its destination at San Francisco it was found damaged as a result of the delay in Seattle.

The court said that facts and oral evidence were admissible to explain ambiguity and to show the circumstances of the execution of the contract. Facts which were not inconsistent with the terms of the bill of lading might be adverted to to make clear what was not clear in the contract.

Again, a steamship bill of lading, providing for carriage of the products to the port of San Francisco and for delivery "there" to order, or at the vessel's tackles to another carrier on the route to destination, if consigned beyond a port of call, and by the connecting carrier to be transported into the port of San Francisco, did not restrict delivery to another carrier to such delivery at San Francisco, but, where San Francisco was not a port of call, authorized such delivery at another port.

And a steamship bill of lading providing for carriage to the port of San Francisco, to be there delivered unto order or at the vessel's tackles to another carrier, and referring to a condition on the back thereof which provided that the goods might be transhipped at any port, and for that purpose might be stored in bulk or craft, or landed, authorized the landing of the goods at Seattle for the purpose of transshipment to San Francisco, which was not a port of call.

Weir Measurement of Liquids

BY L. G. CHASE

THERE are many reasons for close and accurate measurement of all the elements entering into the manufacture of various products under present-day conditions. While production costs are at present decreasing somewhat in certain fields, there is little chance of great reductions for years to come. In modern industrial plants, with their complex departmental systems of supply from one central source or stockroom, it is necessary, to secure accurate records of production costs, that the amount of liquids used in the various processes be carefully measured. These liquids are usually handled in such quantities that it is not possible actually to weigh them and due to their corrosive and

FIG. 1. GRAVITY FLOW METER

Operation: Float 1 raises or lowers rackrod 2, indicating on scale 4 height of liquid flowing over V-notch 3. Drum 5 connected by pinion 6 with rackrod 2 indicates rate of flow at any moment in pounds or gallons per hour. Twenty-four-hour chart 7 records flows graphically. Cumulative readings are shown by integrator 8.

chemical action in most cases they cannot be measured by any ordinary type of meter.

For instance, meters which involve the principle of measuring the velocity of the liquid flowing in closed lines cannot be used at all in most cases, because they depend on a mercury valve to compensate for the differential or velocity head. Most chemicals would combine with this mercury in some form or the working parts of the mechanism coming in contact with the liquid could not be made of such material as would withstand the chemical action. Displacement meters would come under this same head. There is left for us, then, only the weir type of meter. This particular type has one disadvantage—it can be used only where gravity flow conditions are possible, but such a condition can usually be arranged for in services such as those contemplated.

V-NOTCH TYPE WEIR

The weir type meter exists in many forms, but the V-notch type has been found to be the best adapted for accurate measurements of the relatively small volumes which would obtain. The formula of the V-notch was

FIG. 1. LEA RECORDER

1. Measuring the height of water flowing over the weir. 2. Cam drum giving instantaneous indications of the rate of flow. 3. Graphic recorder. 4. Integrator.

same proportionately for any height over the notch, and therefore a fixed constant can be used. This is the constant which Thompson determined. Of course, the flow of liquid over any gravity weir is proportional to the area times the velocity times a constant. The area of a right-angled notch is equal to the square of the height. The velocity is of course equal to the square root of $2G/H$ where H is the height. The square root of $2G$ can be combined with the constant due to any contractions, and we therefore have the foundation of the formula, the quantity equals a constant times H^2 into the square root of H , or a constant times $H^{3/2}$.

With the weir or V-notch type meter, it is possible to have all parts in actual contact with the liquid made out of materials which are not subject to chemical action. For instance, in the measurement of sulphuric acid, a wooden measuring tank can be provided with a sheet lead lining and the float rod and notch plate can be made of glass. For the measurement of caustic liquors, steel can be used throughout. If it is desired to measure milk or substances of like nature, which require extreme cleanliness, measuring tanks, notch plates and

derived by Prof. James Thompson about sixty years ago. Recent exhaustive experiments have served only to prove his high engineering ability and the extreme accuracy with which he worked. The formula he derived is as follows: Q , the quantity of liquid in cubic feet per minute, equals $0.305H^{3/2}$ where H is the height in inches of the liquid passing over a right-angled V-notch. This formula is also true for a notch of any angle less than a right angle in direct proportion to the area. In the ordinary weir the constant used varies as to whether there are any contractions or not and also varies due to the friction of the water passing over the bottom of the notch. It has been found for the V-notch that the resulting friction forces are

FIG. 2. SULPHURIC ACID METER

with this cut. The recording mechanism, which is shown in Fig. 2, furnishes four kinds of information: First, the height in inches of water flowing over the weir. Second, it gives instantaneous indication of the rate of flow. This is suitably inscribed on the cam drum, cut of which is shown in Fig. 3. Third, a graphic paper record is given in pounds or gallons of liquid during any part of a 24-hr. period. Fourth, the integrator shows the total volume flowing between two different readings. In order to check the accuracy of the machine at any instant, it is necessary only to ascertain the height of the liquid actually passing over the notch, from the scale. Knowing this height, it is a simple operation to work out the formula as determined by Prof. Thompson and check the results as shown by the recorder. The cam

all other elements in contact with the liquid can be tinned. Monel is also largely used in making parts to resist the action of various chemicals.

THE LEA RECORDER

We will now briefly describe a commercial type of V-notch meter to show its simplicity and adaptability for this service. Fig. 1 shows the standard type of gravity flow meter for the measurement of any liquid not corrosive to steel. The various parts of the instrument and their uses are briefly described in connection

FIG. 3. GAGE HOUSE FOR BLEACHERY

FIG. 4. CAM DRUM

drum, shown in Fig. 3, has suitably inscribed on it the curve of flow worked out from the power of the head, so that the chart is uniformly divided and equal increments of pen movement on the paper record actual values in volume. This permits the use of any standard type of planimeter in checking the charts.

The integrating device shown in Fig. 2 is driven by a powerful double-spring Seth Thomas pendulum clock. The aluminum disk on which the integrator friction wheel rides is driven by this clock at a speed of two revolutions per hour. The disk is 6 in. in diameter. The integrator and planimetered reading of the chart can be checked within 1 of 1 per cent.

Fig. 4 shows an instrument specially designed for the measurement of sulphuric acid and Fig. 5 an outfit of this kind applied to the measurement of trade waste from a bleachery.

A recording thermometer can be attached to these instruments in such a way that a continuous record can be made of both the quantity and the temperature of the liquid on one chart.

Special propositions, of course, can be worked out for special cases. Measurement of such liquids as sulphuric acid, caustic solution, pyroligneous acid, cyanide, coconut oil, etc., is handled successfully in actual practice.

Philadelphia, Pa.

Repairing Lips and Bottoms of Steel Ladles

Owing to the nature of the smelting process followed at the Nickelton, Ont., plant of the British American Nickel Corporation, the slag obtained sometimes runs high in matte, the action of which is very destructive to steel ladles, tending to wash away the steel at the point of contact and injure the vessel beyond further practical usefulness.

The company has recently been getting economical reclamation by means of thermit welding. The accompanying illustrations and sketches give an idea as to the work done. Pieces of steel were forged and welded to the kettle rather than completely filling up the burnt areas with thermit steel. By this method undue contraction strains were minimized.

In the case of the kettle with the holes in the bottom three forged steel patches and two thermit applications were made as shown in Figs. 1 and 2, owing to the irregularity of the holes and the facility of making two welds easier than one irregular patch. The welding of the bottom was spread over two operations, owing to the fact that there was insufficient material on hand to complete the job the first time. In lining up the patches approximately 1 in. was provided at the edges for the entrance later of thermit steel. These patches were surrounded by a yellow wax pattern and the usual thermit welding practice was then followed.

In arranging riser patterns these patterns were used both inside and outside, one coming off at the high point and two others placed about half way down on the wax. The latter two served to take care of the shrinkage of metal when the weld started to cool.

In the case of welds made on the sides of ladles or kettles (Fig. 3) care must be taken not to put too much stock in the collar of the weld, otherwise there would be a tendency to retard the cleaning or "skulling" of the kettle. In applying the wax collar the wax should be from $\frac{1}{4}$ in. to $\frac{3}{8}$ in. fuller than finished shape in order to allow for shrinkage during contraction.

In forging the lip patch the blacksmiths followed the

FIG. 2. METHOD OF WELDING KETTLE BOTTOM

New Trenching Machine

Construction companies or plant managers contemplating new plants or additions to present properties will note with interest the new multipedal trencher of the Austin Machinery Corporation of Chicago shown herewith. This machine is designed after the fashion of military tractors to operate through heavy friction clutches on each side, to turn practically within its own radius and to be operated by one man. It is particularly applicable to plant work where new pipe lines are being run underground.

A crew hoist raises and lowers the digging arm automatically, and the endless chain and buckets are of standard type. This hoist also acts effectively, because of its construction, as a lever to force the buckets to dig, by crowding the bucket line against the face of the ditch or cut.

A cleaning device takes care of the sticky dirt and scrapes out each bucket as it passes a point at the head of the excavator boom, directly over the conveyor belt. This can be adjusted to deliver the excavated material to either side of the machine.

The gasoline engine is of four cyl. four cycle type, cooled by an inclosed radiator.

The digging width, with 18-in. buckets, will run from 20 in. to 28½ in. and with 24-in. buckets from 26½ in. to 29 in. The standard boom will dig up to 6 ft. in depth, although the machine is substantial for service with an extensive equipment for digging 8 ft. deep. The traction accommodates itself to irregular surfaces, as the equipment consists of two oscillating multipedals. Each one of these multipedal tractions is driven independently by a friction clutch, so that in turning in a confined space one may be stopped while the other is going ahead, turning the machine practically within its own length.

FIG. 1. PATCHES IN PLACE BEFORE APPLICATION OF WAX COLLAR

FIG. 3. SHOWING THE LIP BURNT AWAY BY HOT MATTE

FIG. 5. WELDED LIP BEFORE REMOVING RISERS AND POURING GATE

MULTI-PEDAL TRENCHING MACHINE

The conveyor belt is reversible, so that it can deliver dirt on either side. Adjustable screws are provided for taking up the slack.

An important feature of the working performances is its easy interchangeability for digging trenches with vertical banks or small ditches with sloping sides.

Synopsis of Recent Chemical & Metallurgical Literature

Unknown Points in Rail Manufacture.—C. W. GENNET, JR., of the firm of Robert W. Hunt Co., read an interesting paper before the Western Society of Engineers, Chicago, Nov. 18, 1920, in which he asked the following pertinent questions, which must sooner or later be answered, most probably in large part by metallurgists—that is to say, men interested in quality in metal:

1. Are rails made of steel by the continuous Talbot furnace process comparable with those made by the straight open-hearth method? In the continuous process the furnace is seldom emptied by a hundred tons or so of steel and is tapped every two hours, as against the ten hours of time required to make an equivalent heat in a regular furnace. Is the steel from the rapid-working Talbot furnace sufficiently free from oxides and other impurities to afford good, sound rails?

2. How can such a matter be quickly proved?

3. What effect, if any, on rails has steel made by the duplex process, wherein highly oxidized metal is added to the open-hearth furnace, sometimes very soon before tapping?

4. How can rails rolled from steel containing excessive amounts of impurities be detected?

5. What effect on rails is produced by recarburizing the steel in the ladle with coal or coke and then adding cold deoxidizers to the ladle?

6. What is the real effect produced by holding a ladle of steel prior to casting the ingots to permit time for the chemical reactions to settle?

7. What is the effect on rails rolled from ingots cast with running stoppers and sometimes without any

control by the ladle operator? How does the size of the nozzle, pouring temperatures and time required to cast the ingots of a heat influence rails?

8. How soon after casting ingots should they be charged into the soaking pits in order to assure a minimum of piping and segregation? What effects are produced by delays in promptly charging the ingots to the pits, and what is the effect of unduly and rapidly chilling the outside or skin of the ingots?

9. How long a time and under what conditions of gas and air regulation should ingots remain in the soaking pits? What kind of control of the pits is best to insure against overheating or burning the ingots?

10. What is the effect of rolling rails from ingots one side of which has been heated so hot as to show a bright white spot significant of overheating?

11. What effect on rails have different rates of blooming the ingots? In some cases 8 x 8-in. blooms are made from ingots in nine passes and in other cases in twenty passes. Some mills work rapidly and others slowly; does this produce any difference?

12. What effect on the grain structure or the life of rails is produced by increasing the number of passes, or work given to the steel, when the ingots are rolled into rails? One mill makes a rail from a 19-in. square ingot in fifteen passes, while another mill makes the same rail from a 24-in. square ingot in twenty-nine passes. Has the average rate of reduction per pass any effect on the life of rails?

13. What matters mostly influence the production of rails showing seams on the surface? Some heats are practically free from indications of seams, while on other heats rolled at the same time seams are abundant.

Photography of Colored and Distant Objects.—In his first address as president to the London Section of the Society of Chemical Industry, Sir WILLIAM J. POPE discussed the photography of colored and distant objects. His address is printed in full in the Nov. 15 issue of the society's journal. In demonstrating the value of a spectroscopically pure red filter between the lens and a distant object to bring out greater detail, he availed himself of a familiar phenomenon with happy facility.

"The atmosphere," he said, "is not penetrated with equal facility by light of all colors or of all wave lengths. The rays of short wave length, the blue and violet, are most readily absorbed and diffused by the air, and, in passing from short to longer wave lengths, through the green and yellow to the red, the absorptive and diffusing effect of the atmosphere becomes progressively less and less.

"A simple demonstration of the truth of this statement is presented to us every day. When the sun is high it appears white or bluish-white; and its outline is sharp; but as the sun declines it appears yellow and loses its sharpness of definition. Just before the sun falls below the horizon it is bright red and shows a hazy outline. So that with perpendicular incidence the sun's light reaches us with but little absorption of the blue rays by the short lengths of atmosphere through which it has to pass. As the sun declines the blue is absorbed by the longer stretch of air, and just at the setting the atmospheric path through which the sun's rays reach us is so long that the blue, green and yellow are absorbed and diffused and nothing reaches us but the red light. The same thing happens in a fog; if the fog is slight the sun appears yellow and not sharply

defined, but if the fog is dense the sun shows red, and its circle is very indistinctly defined.

"These facts, based upon common observations, have a very important bearing. If a distant view is photographed on an ordinary plate sensitive only to the blue and violet, absorption and diffusion of the light are considerable; the resulting photograph is thus more or less ill-defined. But since the atmosphere is penetrated to a far greater extent by the red rays, it follows that if a spectroscopically pure red filter is placed between the lens and the object, the resulting photograph will reveal far more detail."

Intercrystalline Fracture in Mild Steel.—WALTER ROSENHAIN and D. HANSON, of the National Physical Laboratory, presented a brief note on the above subject before the British Iron and Steel Institute, Sept. 21, 1920. Investigations of several hundred fractures in mild steel convince them that fracture (except at very high temperatures) is by breakage across the ferrite crystals rather than between them. They now describe four noteworthy failures which are mainly intercrystalline, three from high-pressure steam boilers, and one from a tube in intermittent service in hot niter.

Case I (0.14 C) was from the combustion chamber of a marine boiler, showing severe cracking at the edges between rivet-holes, associated with low elastic limit, elongation and impact. The cementite was collected in thin layers at the boundaries of ferrite crystals. Normal results were obtained in all tests from the central part of the plate.

Case II (a boiler drum) cracked around the edges, starting from rivet-holes. Physical properties, edge to center, were little different, and the microstructure showed only part of the cementite as intercrystalline films; yet the cracks seemed to be most numerous in those portions of the plate containing the most free cementite.

Case III. Cracks in all plates, but especially the outside cover, in a boiler seam. Physical and microscopic tests revealed no abnormality. Sheared rivets (almost carbon-free) from the same joint also showed intercrystalline cracking. A piece of the sound plate was torn apart, but this fracture went across the grains—intercrystalline weakness appears to be associated with stresses operating for a period of years rather than minutes.

Case IV developed in mild steel tubing after six months' intermittent service without working stress in a niter bath at 300 deg. C. These cracks were badly corroded. Microstructure exhibited globular cementite, often noted in cold-drawn steel tubing annealed several times below the critical range.

This last failure is similar to season cracking, since only internal stresses are in operation. The three failures in boiler plates can hardly be ascribed to stresses set up during bending; forcing a fit seems a more likely source of serious internal stresses. All cases occurred after long-continued heating a prerequisite for this type of failure in steel as far as present information goes. Corrosion is a subsidiary cause and an accelerator, selectively attacking the intercrystalline cement and therefore weakening cohesion. Proper normalization of structure by proper heat-treatment does not seem to prevent intercrystalline failure, since Case III showed no microscopic abnormality, other than a banded arrangement of the pearlitic areas—if this can be regarded as an abnormality.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Utilizing Vegetable Refuse.—Refuse from fruit and vegetables, such as pea and bean pods, banana skins, and especially asparagus waste, is treated to obtain fibers suitable for spinning, food or flavoring material, and manure. The waste is crushed with water between rollers and then placed, with the extracted juice and water sufficient to cover it, in an autoclave, where it is heated under pressure for between two and three hours. The fibers are then strained free from the juice and again passed between rollers. They can then be dried and used for coarse weaving, ropes, etc., or they may be boiled with an alkali for two or three hours, washed, pressed and dried, when they are suitable for finer fabrics. The solid residue can be used for manure, either as it is, or after drying and neutralizing the alkali. The liquor is evaporated to any desired consistency, or to dryness, and can be used for making vegetable-soup cubes, seasonings, sauces and the like. (Br. Pat. 147,833, not yet accepted; W. MATZKA, Brunswick, Germany, Oct. 13, 1920.)

Aluminum Alloys.—Aluminum is alloyed with lithium, which may be partly or wholly replaced by barium or strontium, with or without the addition of other metals such as copper, zinc, manganese, tin, etc. The alloy may contain up to 40 per cent of lithium, and may be annealed one or more times by heating to over 100 deg. C. and cooling in air or liquid, or otherwise. (Br. Pat. 147,903, not yet accepted; METALLBANK UND METALLURGISCHES GES., Frankfurt-on-Main, Oct. 13, 1920.)

Molding Cellulose Acetate.—Relates to the production of molded articles from cellulose acetate and consists in subjecting the material in a finely divided state, preferably in the presence of very small amounts of low-boiling or volatile substances, to a high pressure at a temperature approaching the decomposition point and allowing to cool under pressure. The operation may be carried out at a lower temperature and pressure by adding 2 to 5 per cent of water, alcohol, etc., or solid substances such as naphthalene or camphor. Preferably the material obtained by a first pressure is disintegrated and subjected to a second pressing operation. In this case, the cooling under pressure may be omitted by providing the mold with channels, nozzles or slots of small diameter, through which the hot material is forced under pressure in the form of filaments or ribbons. The disintegrated material may be mixed with large quantities of mineral powders—e.g., two to five times the amount of cellulose acetate—before applying the final pressure. The material may be molded with inlays of wood, ebonite, etc. (Br. Pat. 147,904, not yet accepted; CELLON-WERKE A. EICHENGRUN, Berlin, Oct. 13, 1920.)

Fatty Acids.—The unsaturated aliphatic hydrocarbons contained in mineral oils or the liquid or gaseous products of their distillation or cracking, in natural

gas, in the liquid or gaseous products of the destructive distillation of coal, wood, peat, shale, shale oils or tar oils, or in carburetted water-gas, oil-gas, water-gas tar, oil-gas tar, lignite tar, producer gas, coal-gas, etc., are converted into fatty acids by first treating the gases, oils, etc., with mineral acids (sulphuric, hydrochloric, etc.) whereby the unsaturated hydrocarbons are converted into esters, and then treating these esters with oxidizing agents. For example, the acid sludge or acid resins obtained in refining mineral oils with sulphuric acid are treated with potassium bichromate and sulphuric acid. Volatile fatty acids formed are distilled off with steam, and the non-volatile fatty acids remaining are freed from chromium oxide by boiling with dilute acid and may be converted into soaps by alkali. Acid anhydrides may be formed in the oxidation process, these also being converted into soaps by alkali. The more volatile acids (butyric, valeric, etc.) may be converted into esters for use in perfumery. (Br. Pat. 147,905, not yet accepted; H. STRACHE, Vienna, Oct. 13, 1920.)

Ethylene Chloride.—The ethylene content of coal-gas, or other gases produced by the distillation of carbonaceous matter, such as lignite, oils, etc., is utilized for the production of ethylene chloride by treating the gases with chlorine in the presence of a suitable catalyst, and separating the ethylene chloride from the treated gas by liquefaction by compressing, cooling, etc. (Br. Pat. 147,909, not yet accepted; GOLDSCHMIDT AKT. GES., Essen, and F. BERGIUS, Berlin, Oct. 13, 1920.)

Cuprous Oxide.—Cuprous oxide is obtained by blowing air through liquid refined copper until the desired stage of oxidation is effected. The cooled material may be ground; it is suitable for the production of copper salts and cuprammonia solutions. (Br. Pat. 147,958—1919; HÜTTENWERK NIEDERSCHÖNEWEIDE AKT. GES. VORM. J. F. GINSBERG, Berlin, Oct. 13, 1920.)

Catalysts for Hydrogenating Fats and Oils.—Non-pyrophoric metal catalysts adapted for use in the hydrogenation of fats and oils are prepared by precipitating a solution of a salt of a catalytic metal with a solution containing a usual precipitant such as soda or caustic alkali, together with borax, and then reducing the precipitate in a current of hydrogen. In examples, a solution of nickel chloride is precipitated with a solution containing soda and borax so as to give a precipitate of nickel carbonate and borate; which is afterward dried, heated to decompose the carbonate and then reduced in hydrogen; a solution of protoxide of nickel dissolved in hydrochloric acid is mixed with kieselguhr, and precipitated with a solution containing soda and borax, and the precipitate then reduced as usual; a cobalt salt solution is mixed with kieselguhr and precipitated with a solution containing a usual precipitating agent and borax, and the precipitate is washed, dried and reduced in hydrogen. (Br. Pat. 148,111, not yet accepted; MÜLLER SPEISEFELTFABRIK AKT. GES., Neukölln, near Berlin, Oct. 13, 1920.)

Extracting Alkali-Metals.—Alkali-metals are obtained by heating a halogen salt of the metal with an alkaline-earth compound such as a carbide, hydride or silicide. For example, a mixture of sodium chloride and calcium carbide may be heated in a vacuum first to 350 deg. C. and afterward to 800 deg. C., whereupon sodium distills to the colder parts of the apparatus. A

high-quality lampblack is formed as a byproduct. (Br. Pat. 148,122, not yet accepted; L. HACKSPILL and C. STAHLING, Institut de Chimie, Strasbourg, Oct. 13, 1920.)

Wood Preservative.—Mercuric chloride solution is rendered more effective as a wood preservative by mixing with it a solution of a fluorine salt such as sodium fluoride, a fluosilicate or a mixture of fluorine compounds with fluosilicates. The specification states that the mercuric chloride is converted into complex salts. The salt solutions may be applied separately to the wood. (Br. Pat. 148,137, not yet accepted; F. BUR, Petershagen, near Berlin, Oct. 13, 1920.)

Synthetic Tanning Agents. Synthetic tanning agents are prepared by sulphonating the alkali-soluble fractions of anthracene oil or soft pitch, and condensing the sulphonic acids with aromatic sulphochlorides in alkaline solution. According to an example, the parent substance is sulphonated with sulphuric acid monohydrate, the product dissolved in water and neutralized with caustic soda, sodium sulphate is removed by evaporation, and the concentrated solution is mixed with caustic soda and treated with toluene sulphochloride in benzene solution. (Br. Pat. 148,268, not yet accepted; M. MELAMID, Freiburg, Breslau, Oct. 20, 1920.)

Anthraquinone Derivatives.—A vat dye, giving claret-red shades, is obtained by condensing hydrozine or a salt thereof with 1-amino-anthraquinone-2-aldehyde or the azomethine compounds thereof. The parent azomethine compounds are obtained by heating 1-amino-2-methylantraquinone with aromatic nitro compounds and alkalis, with or without the addition of primary aromatic amines; 1-aminoanthraquinone-2-aldehyde results on hydrolyzing these azomethine compounds by acids. (Br. Pat. 148,339, not yet accepted; L. CASSELLA GES., Frankfurt-on-Main, Oct. 20, 1920.)

Vulcanizing India Rubber.—India rubber is vulcanized in an atmosphere of volatile alkali at atmospheric pressure. The alkali may be ammonia or a volatile organic alkali, and it may be diluted with an inert or reducing gas or a mixture of these, such as hydrosulphuric acid and carbonic acid. The addition of litharge is thus rendered unnecessary, and the color of mixings preserved. The temperature of vulcanization may be about 145 deg. C. (Br. Pat. 148,349, not yet accepted; E. TILCHE, Paris. See also 148,350, Oct. 20, 1920.)

Obtaining Liquid Products From Coal.—In obtaining liquid products from coal by hydrogenation under pressure coal is used which contains not more than 85 per cent of carbon referred to dry substance free from ash. In an example 5 kilos of coal having a carbon content of 74.48 per cent on the above basis was mixed with 10 kilos tar oil and heated for six hours under a pressure of 100 atm. of hydrogen; 87 per cent of the coal was converted into liquid products, as against 11 per cent of a coal with a carbon content of 92.1 per cent similarly treated. (Br. Pat. 148,436, not yet accepted; F. BERGIUS, Berlin, Oct. 20, 1920.)

Ferrochromium.—Ferrochromium, low in carbon or in carbon and silicon, is made by transferring molten high-carbon ferrochromium from a blast furnace into a converter, which may be acid-lined, and blowing therein with or without the addition of lime or other basic materials, or the injection of steam or other gas or vapor into the blast. (Br. Pat. 148,456, not yet accepted; F. KRUPP AKT. GES., Essen, Oct. 20, 1920.)

Current Events

in the Chemical and Metallurgical Industries

Isopropyl Alcohol From Petroleum

A meeting of unusual interest was held by the New Jersey Chemical Society at Stettens' Restaurant, Newark, Monday evening, Dec. 13. C. L. Bryden, chairman of the committee on membership, reported twenty-seven new applicants. These were duly elected, bringing the membership to a total of nearly 550. A petition to Congress urging immediate action on the dye bill was drawn up and Williams Haynes, publisher of *Drug and Chemical Markets*, was called upon to discuss the status of the bill. In pointing out the danger of Germany dumping dyes in this country he called attention to the situation in regard to potassium bromide. The pre-war price of this chemical was 30c. per lb. American-made bromide is now being sold for 45c. per lb., but the Germans are offering it at 20c. for spot, with future delivery as low as 15c.

ARTISTIC PAINTING

Maximilian Toch delivered an entertaining and instructive address on pigments and paints used in ancient and modern artistic painting, including a discussion of the methods used in determining the genuineness of an old painting.

INSTITUTE OF CHEMISTRY PROPOSED

A report of the committee on an Institute of Chemistry was read by the chairman, who said that the tentative plan had been prepared in order to get opinions from all interested. The matter had been brought to the attention of several, but the publication of the report would reach a much larger number. The ideas of the committee were open to changes and suggestions, considerable interest had been shown, and it seemed best to set forth a definite scheme, which would be a basis for a further report.

In answer to several questions the chairman said that there seemed to be no one of the ten or more professional societies which either could or would undertake this matter, but that an offer to do so would be welcome. One very definite suggestion has already been made, that the project for the State of New Jersey be undertaken by the New Jersey Chemical Society. As far as the list making, which was the first step, was concerned, this was already under way; the next step, that of registration, would be considered by the committee. The further suggestion that probable vacancies in the chemical industries be reported to the Society, which would then bring them to the attention of unemployed members, would also be considered.

The report of the committee follows, and the views of all who are interested will be welcome:

At the October meeting of the New Jersey Chemical Society a paper was read which pointed out the need of a closer affiliation among chemists, and it was resolved that a committee be appointed to take action to ascertain if it is advisable to form an American Institute of Chemistry.

Such an organization could:

1. LIST, on request, and without charge: (a) all persons who wished to be considered chemists, in any sense of the word; (b) all chemical products; (c) all chemical industries, these lists to be public.

2. REGISTER any chemist who would furnish a certain amount of definite, accurate information as to education and experience, such information and all other pertinent facts to be subject to independent investigation and to be available to inquirers under reasonable regulations. For registration a moderate fee would be charged.

3. CERTIFY chemists of various kinds of chemical education and experience after the candidate had passed a definite examination suited to the grade of certificate desired. For these examinations reasonable fees would be charged.

4. LEGALIZE the practice of chemistry in its various grades, by securing the proper legislation in national and state legislatures.

5. CO-OPERATE with all institutions training chemists in order to harmonize courses of instruction, and with institutions and chemical societies to interest employers in properly trained chemists, without, however, acting as an employment agency.

Such an Institute of Chemistry would, in the first instance, consist of a self-perpetuating body of, say, fifty chemists, nominated by the existing chemical organizations, with the understanding that after five years one-half the vacancies would be filled from the certified chemists, after ten years all vacancies would be so filled.

We would be glad to have your definite opinion upon the following:

Should an Institute of Chemistry be established?

If so:

Should it function as outlined?

What else, if anything, should it do?

Should it be constituted as outlined?

How should it be financed?

If not, should anything be done?

If so, what?

Replies should be addressed to F. D. Crane, 74 N Willow St., Montclair, N. J.

ISOPROPYL ALCOHOL FROM PETROLEUM

Carleton Ellis, president of the Society, was introduced by Dr. R. P. Calvert, who took this opportunity to tell the members of Mr. Ellis' work on paint and varnish removers, hydrogenation of oils, recovery of potash from silicate rocks, and the preparation of cumarone resins, which are so extensively used in chewing gum manufacture. Mr. Ellis spoke on the development of his process for producing isopropyl and other alcohols from petroleum.

To make petroleum the raw material for a series of chemical products has been the aim of scores of research chemists. Chlorine has been the reagent employed in many cases to attack members of the paraffine series. Thus, chloropentane serves as an intermediate for the production of amyl alcohol by saponification, or for the production of amyl acetate by treating with sodium acetate in an autoclave. One of the difficulties has been to limit chlorination to the desired compound.

In the manufacture of gasoline by cracking processes many unsaturated compounds are formed and the gases which escape from the pressure stills are found to contain 2 to 3 per cent ethylene, about 5 per cent propylene, and 1 per cent of higher olefines, such as butylene, amylene, hexylene and heptylene. About 1 per cent of H₂S is usually present, although this may be higher when Mexican oils are being treated. Ordinarily these gases are simply used as fuel. One refinery produces over 10,000,000 cu.ft. per day, containing 10 to 12 per cent olefines.

Research on the utilization of the olefine content of these gases was started in the hope of finding a fusel oil substitute. After much experimentation it was

found that isopropyl alcohol could be obtained. An organization, the Melco Chemical Co., was formed for development work and a small plant was built near the Bayonne plant of the Tide Water Oil Co., which furnished the gases from its pressure stills. Later the Standard Oil Co. of New Jersey secured the rights to the process and is now producing isopropyl alcohol under the name of petrohol at its Bay Way refinery. M. D. Mann, Jr., of the company's chemical products division, is in charge.

MANUFACTURE OF ISOPROPYL ALCOHOL

The process depends upon the reaction between propylene and sulphuric acid to form propyl hydrogen sulphate, which hydrolyzes upon boiling the diluted solution, yielding isopropyl alcohol:

Removing hydrogen sulphide and water vapor from the gases constitutes the first step. The olefine vapors are then absorbed in 87 per cent H_2SO_4 (sp.gr. 1.8), the temperature being maintained between 15 and 20 deg. C. by refrigeration. Strength of acid and temperature must be controlled within narrow limits if the formation of tarry polymerization products is to be avoided. At the end of the reaction the specific gravity has fallen to 1.4 and there has been an 80 per cent increase in volume. Unabsorbed gases are used for fuel.

Any oil which may have been entrained in the acid solution is removed in settling tanks. About four volumes of water are added, reducing the strength of the acid to about 15 per cent H_2SO_4 . This separates the tarry polymers.

Hydrolysis is completed and the alcohol separated by distillation in lead-lined stills. During distillation olefines are regenerated, sometimes to the extent of 20 per cent of the amount originally absorbed. These are returned for re-absorption.

The crude product is a mixture of several alcohols (with small amounts of ethers) and is, therefore, rectified to give isopropyl alcohol and several byproducts.

PROPERTIES OF ISOPROPYL ALCOHOL

A comparison of the properties of isopropyl alcohol and ethyl alcohol indicates the close relationship between these compounds:

	Isopropyl Alcohol	Ethyl Alcohol
	Constant Boiling Mixture	
Boiling point, deg. C.	80.37	78.15
Per cent by volume.	90.3	97.3
Specific gravity.	0.8190	0.8060
	Pure Compound (Absolute)	
Boiling point, deg. C.	82.41	78.30
Specific gravity.	0.7855	0.7893

Petrohol is the constant boiling mixture containing 90.3 per cent by volume of isopropyl alcohol and boiling at 80.2 deg. C. It may be used in place of ethyl alcohol for solvent purposes. It is not suitable for beverage purposes and is thus not subject to Government restriction. Physiological tests indicate that inhalation of the vapors produces less harmful results than ethyl alcohol or methanol.

During the war all possible sources of acetone were investigated. It was found that acetone could be made from isopropyl alcohol by catalytic oxidation or by dehydrogenation:

The Bureau of Aircraft Production took over the

plant for a time and prepared acetone by the first method, using copper as a catalyst.

Isopropyl acetate has been produced by a process similar to the direct method for amyl acetate:

No attempt is being made at present to recover the ethylene in the still gases, since the formation of ethyl hydrogen sulphate requires higher temperature and more concentrated acid, which cause excessive polymerization.

Motor Fuel Symposium at the Meeting of the Washington, D. C., Section, A. C. S.

Four prominent speakers and an extended discussion aroused a great deal of interest at the 312th meeting of the Chemical Society of Washington Thursday, Dec 9, when the entire program was devoted to a symposium upon the present status and future prospects of motor fuel supply.

A. W. Ambrose, chief petroleum technologist of the Bureau of Mines, discussed petroleum products for motor fuel supply. He described the three classes of investigators of this subject as pessimists, optimists and super-optimists. The pessimist believes the problems cannot be solved; the super-optimist believes there is no problem. Neither of these classes is right, in Mr. Ambrose's opinion. The optimist believes that there is a problem of difficulty, but that it can be solved by proper planning.

The present gasoline requirements of the country indicate a need for 4 to 4.5 billion gallons of motor fuel for 1921. This represents many times the demand of ten years ago, but the crude oil available from domestic production is only about twice that of ten years ago. The output of motor fuel has been increased from petroleum by better recovery of crude, by higher percentage recovery of motor fuel during refining and by conservation in use of fuel. Efficiency on the part of the ultimate user is the most promising means of relief of the shortage.

Shale oil development, still in its infancy as a commercial business, offers little encouragement for the immediate present because of the difficulty of economical retorting to secure an easily refinable product for motor fuel production.

W. M. Rile of The Barrett Co. discussed the subject of coal-tar products as a source of motor fuel, especially motor benzene. This is really a mixture of benzene, toluene and xylene. Typical specifications for motor benzene are 0.878 specific gravity, neutral reaction, sulphur not exceeding 1 per cent, ability to pass the "doctor" test and the gumming test, and distillation as follows: first drop 79 to 80 deg. C., 60 per cent below 100 deg. C., 90 per cent below 121 deg. C., dry at 135 deg. C., with no appreciable residue. Because of the greater vapor tension at a given temperature and materially higher heating value of benzene per gallon as compared with gasoline, distinct advantages in the way of thermal efficiency and miles per gallon are experienced. However, under present conditions the total available motor benzene supply of the country even if all light oil from byproduct coking and city gas plants equipped for light oil recovery be included, is barely 2 1/2 per cent of the gasoline requirements of the country. By extreme measures, including byproduct recovery from all coal coked, stripping of all city gas supplies for light oil and other increases to be expected during the next few years

in these lines, we cannot expect much over 5 to 10 per cent of the gasoline demand of today to be met from motor benzene as this term is now used.

Industrial alcohol as a motor fuel was discussed by B. R. Tunison, of the Industrial Alcohol Co. The present output of this product which might conceivably be diverted into motor fuel use if the requirements for solvent and chemical operations were ignored is approximately the same order of magnitude as the total available motor benzene. The estimated industrial alcohol plant capacity of the entire country is only about 100 million gallons per year—that is, about 2½ per cent of the motor fuel requirement of today.

The carburetion characteristics of alcohol, benzene and gasoline were contrasted by Dr. Tunison, and it was shown why the blended fuels including some of each of these three constituents could be expected to give superior motor performance. The great advantage of alcohol for motor use is that it fires quickly but does not increase its rate of burning as much during combustion as do the other motor fuels. Moreover the range of fuel: air ratio for successful operation is wider with alcohol than with either benzene or gasoline. Alcohol also permits much higher compression ratios, thus giving large possible increase in efficiency under the most favorable conditions, but it is not under normal circumstances best applied alone. It lends itself rather to the blended fuel application.

Forest products as a source of alcohol for motor fuel was discussed by a paper prepared by E. C. Sherrard, of the U. S. Forest Products Laboratory, presented by Dr. H. F. Betts, of the Forest Service. The possibilities of alcohol production from wood waste were fully set forth. It was pointed out that this was one of the most promising sources of cheap raw material for industrial alcohol production. The estimates indicated that about 15 gal. of alcohol could be expected under ordinary conditions of plant operation per ton of wood treated. The investigations of the Laboratory on the best conditions for cooking wood pulp with acid as the initial stage in alcohol production were discussed also in this paper.

The discussion brought out by questions and contributions from numerous members of the Society emphasized many of the economic aspects of the case, particularly the difficulty of control of living reagents such as the bacteria for fermentation, the necessity for utilization of some sugar-containing waste materials for feeding stuffs instead of for alcohol production, and the severe limitation of any alcohol production if waste materials are not cheaply available. The advantages of coal as a raw material for liquid fuel manufacture and the necessity of adapting the engine to available fuels rather than insisting that fuels must be made to suit present-day engines was also stressed.

Connecticut Valley Branch of T.A.P.P.I. Holds Meeting

The regular monthly meeting of the Connecticut Valley Branch of the Technical Association of the Pulp and Paper Industry was held in the Social Rooms of the American Writing Paper Co., Holyoke, Mass., on Dec. 13. It was in the nature of an experience meeting, the members bringing their troubles along for discussion. Among the topics presented were the presence of beater gum, the intensification of colors in paper after standing around for a short time, slack sizing on one side of machine-finished paper and standard practice of heating.

December Meeting of Connecticut Valley Section, A.C.S.

The regular monthly meeting of the Connecticut Valley Section, A.C.S., was held at the Highland Hotel, Springfield, Mass., on Dec. 11. After dinner and a short business meeting, Prof. Harold Hibbert of the Sheffield Scientific School, Yale University, spoke on "The Constitution of Cellulose." Much of the subject matter of Professor Hibbert's lecture has already appeared in abstract form in *CHEMICAL & METALLURGICAL ENGINEERING* (Sept. 22, 1920; vol. 23, p. 563). In addition, the lecturer discussed the recent work, particularly that of Hess, that has been published since he read his paper at the Chicago meeting of the A.C.S. The address proved to be very interesting, especially to the large number of paper-makers present, and provoked a discussion that lasted about forty-five minutes, much of which was devoted to colloid chemistry.

Patent Bill in Conference

The Patent Office bill with its Senate amendment providing for the administration of Government-employee patents by the Federal Trade Commission has reached the conference stage. There was some opposition on the part of a few members of the House in allowing the measure to go to conference on the plea that the salary increases in the Patent Office are not justified. None opposed the bill on the ground that it contained the Senate amendment. The conferees on the part of the House are Representatives Nolan, the chairman of the committee; Mr. Lampert of Wisconsin and Mr. Davis of Tennessee. The conferees on the part of the Senate will be Mr. Norris, the chairman of the committee; Mr. Brandegee of Connecticut and Mr. Kirby of Arkansas.

Tariff Hearings to Be Held

The tariff schedule covering chemicals, oils and paints is to be the subject of a hearing before the Committee on Ways and Means of the House of Representatives on Jan. 6, 7 and 8. In order that a tariff bill may be ready to be introduced at the opening of the extra session, the Committee on Ways and Means intends to complete the hearings and draft the bill between now and the opening of the session. The hearings on earthenware, earthenware and glassware will be held Jan. 10 and 11. The schedule covering metals will be the subject of hearings on Jan. 12, 13 and 14. Hearings on the sugar schedule are set for Jan. 18 and 19. The hearing at which the free list will be taken up is scheduled for Feb. 11, 12 and 14.

To Study Federal Reorganization

The resolution providing for the appointment of a joint Congressional committee to study the departmental machinery with the idea of recommending a form of reorganization is at this writing in the hands of the President, awaiting signature or veto. The House on Dec. 14 passed the resolution which had been adopted by the Senate at the last session. This allowed its immediate transmittal to the White House. Should this resolution become a law, it will be regarded as a distinct advantage for those favoring the creation of the Department of Public Works. As the committee likely to be chosen is expected to report its recommendations soon, it is believed that this will improve the chances of securing action on a reorganization bill.

Standardization of Industrial Laboratory Apparatus

Through the efforts of certain apparatus manufacturers, there met informally at the Chemists' Club, New York City, on Aug. 2, representatives of the following companies to discuss the advisability of drawing up standard specifications for laboratory apparatus to be used in their industrial research and works control laboratories: Barrett Co., General Chemical Co., Atmospheric Nitrogen Corporation, Grasselli Chemical Co., National Aniline & Chemical Co., New Jersey Zinc Co., Solvay Process Co., Standard Oil Company of New Jersey, and E. I. du Pont de Nemours & Co.

It developed at this meeting that material savings might be expected to develop from this work. Since most of these companies are members of the Manufacturing Chemists Association of the United States, a committee composed of these members was appointed by the Manufacturing Chemists Association to pass on the proposals of the informal committee and to recommend the adoption of the specifications resulting from the informal committee's work as standard for the members of the Manufacturing Chemists Association.

Arrangements have been made for full co-operation with the Committee on Guaranteed Reagents and Standard Apparatus of the American Chemical Society, and also with the Committee on Standards of the Association of Scientific Apparatus Makers of the United States of America. These specifications will be considered carefully by committees of these three societies, and it is expected that they will then be published as tentative for a period of six months in order to give time for general criticism. At the end of that time the specifications will be adopted as final.

In carrying on this work an effort will be made to obtain specifications which will insure the cheapest mode of manufacture of a given instrument consistent with the duties that it must perform.

To date, three meetings of this committee have been held and considerable progress has been made. The committee desires to co-operate fully with all industries, and any communications should be forwarded to the chairman, Dr. E. C. Lathrop, E. I. du Pont de Nemours & Co., Wilmington, Del.

Governmental Reorganization

While the matter of governmental reorganization is a subject of much comment on the part of lawmakers and others in Washington, it is very doubtful whether any consideration will be given to the subject on the floor of either house of Congress at the short session. Senator McCormick, of Illinois, has announced his intention of introducing a bill for the reorganization of the executive departments as a companion measure to his budget bill. This bill is along the same lines as that known as the Jones-Reavis bill. Senator McCormick's bill is not to supplant the Jones-Reavis measure, but it is apparent that no difficulties will be encountered in harmonizing the two measures in committee.

To Push Nitrogen Corporation Bill

Notice has been given in the Senate by Mr. Smith of South Carolina that he will insist upon prompt consideration of the bill providing for the establishment of a self-sustaining federal corporation for the production of atmospheric nitrogen. He expressed the hope that the bill would be acted upon before the holidays.

Forest Service Establishes New District in Alaska

The establishment of a new field district comprising the Chugach and Tongass National Forests in Alaska, with headquarters at Juneau, is announced by the Forest Service, to take effect Jan. 1, 1921. The new district will be in charge of District Forester Charles H. Flory, who is at present Superintendent of National Forests in Alaska. The establishment of the new district was decided upon in order to facilitate the transaction of the growing business of the two Alaskan national forests, and is in line with the policy of decentralized administration of the Forest Service. Nearly all of the business of the Alaskan forests will be transacted in the future on the ground by the district forester and the local forest officers, the officials of the Forest Service state.

The Tongass and Chugach national forests comprise 20,574,000 acres of land and include practically all of the best timber along the coast of Alaska. The sales of timber are increasing steadily and receipts from the two forests for the last fiscal year exceeded \$100,000. With the development of a paper industry, which is now in sight, officials of the Forest Service expect that the receipts will be greatly augmented. A sale for 100,000,000 ft. of pulp wood has already been made to a company which will establish a paper plant, and a sale of 1,500,000,000 ft. is in prospect.

The establishment of a paper-making industry, according to members of the Forest Service familiar with Alaskan conditions, will do much to stabilize the development of the territory. Alaska, it is said, is now in a condition somewhat like that of a worked-out mining camp. The rich placer mines have been exhausted, present prices of metal make it unprofitable to mine many of the lode claims, the salmon fisheries have been depleted, and there is no good market or means of transportation for such agricultural crops as are raised. Yet the undeveloped resources of the territory are very great. A paper industry will be perpetual because the timber on the national forests will be so cut as to insure regrowth, and the establishment of large manufacturing plants with the necessary towns for the workmen will afford steady employment for a considerable number of people, will increase transportation facilities and will create a market for crops produced locally.

The administration of the national forests has already been largely decentralized, the officials of the Forest Service state, but the establishment of a new district in charge of a district forester with large discretionary authority to transact Government business will further facilitate dispatch.

Personnel Changes in Bureau of Standards

During October there were thirty-one additions, twenty-two separations and fifty-nine promotions in the scientific staff of the Bureau of Standards, and during November sixteen additions, eight separations and twenty-eight promotions. Walter A. Hull has been transferred from the work on fire-resistive properties of materials to the Division of Ceramics and placed in charge of the work in connection with the production of optical glass. The resignations included none of the more advanced members of the staff. The additions to the staff included Paul R. Heyl, physicist, and W. L. Simpson and R. A. Webster, associate electrical engineers, and the reinstatement of A. Halsted, associate electrical engineer, William H. Smith and Alfred N. Finn, chemists.

Personal

L. S. CATES, assistant general manager of the Utah Copper Co., has returned to his headquarters at Salt Lake City after a trip to Boston, New York and Florida.

M. HAZEN CHASE has resigned his position as office manager and assistant to the superintendent of the Copescook mill of the S. D. Warren Co., Gardner, Maine, to accept one as assistant to R. R. Campbell, vice-president, in charge of manufacturing, of the American Writing Paper Co., Holyoke, Mass.

HIRAM W. CLARK, consulting engineer of the United States Bureau of Mines at Salt Lake City, has been appointed deputy smoke inspector of Salt Lake City.

J. L. HARMAN has been appointed manager of the El Paso branch of the Mine & Smelter Supply Co.

HERRBERT C. HOOVER spoke before the Chicago Engineers' Club recently.

WILMER H. KOCH, formerly analytical chemist with E. I. du Pont de Nemours & Co. at its Lodi plant, is now in the research laboratory of the Mathieson Alkali Works, Niagara Falls, N. Y.

J. L. OLDRIGHT, formerly superintendent of the leaching division of the Chile Copper Co. at Chuquicamata, Chile, is visiting mining and metallurgical plants in the West.

WILLIAM RUSSELL, London representative of the Dorr Co., who has been in this country several months and who has been visiting Western metallurgical and Eastern industrial centers, sailed for England Dec. 15 on the Adriatic. He was tendered a dinner by thirty members of the Dorr staff on Dec. 14.

DANIEL H. SCHWARTZ, for the past twenty years superintendent at the Chemical Paper Co., Unit 5, Holyoke, Mass., has resigned his position with that company to accept one as general superintendent of the Ironside Board Corp., Norwich, Conn.

HENRY N. THOMPSON, formerly superintendent of the International smelter at Tooele, Utah, has been appointed instructor in metallurgy at the University of British Columbia at Vancouver.

ETHAN VIALI, for ten years on the staff of *American Machinist*, has resigned as editor to become a partner in the firm of T. W. Minton & Co., Barboursville, Ky.

Obituary

ELIJAH PADDOCK HARRIS, emeritus professor of chemistry at Amherst College, died on Dec. 10 at Warsaw, N. Y., after a long period of ill health. Prof. Harris was born in LeRoy, N. Y., April 3, 1832, and spent his boyhood on a farm with four months of school in the winter. He attended LeRoy Academy and the Seminary at Lima, N. Y., and spent the first two years of his college course at Genesee College. He graduated from Amherst in 1855, having entered as a junior, and immediately after graduation spent several years in teaching. In 1859 he received the degrees of A.M. and Ph.D. from the University of Göttingen. He became professor of chemistry and natural history at Victoria College, Coburg, remaining until 1866, when he went to Beloit College. He succeeded W. S. Clark as professor of chemistry at Amherst in 1868, and for forty years was instrumental in training many successful chemists. He retired in 1907 under the Carnegie Foundation at the age of seventy-five. Victoria College conferred upon him the degree of LL.D. in 1890. He was the author of several books on chemistry and was a member of Phi Beta Kappa and Psi Upsilon fraternities.

Current Market Reports

The Chemical and Allied Industrial Markets

New York, Dec. 20, 1920.

Inquiries for chemicals appear to be covering a somewhat larger field, and while it is admitted that there is considerable room for improvement, business is reported of a better volume than in the past few weeks.

Spot *bichromate of soda* was held at 9½c. lb. in most prominent quarters affiliated with resale stocks. Some dealers claim to be able to shade this price slightly and quotations were heard at 9¼@9½c. per lb. for a few odd lots. December shipments were held at 9½c. per lb. works, while January was quoted about 1c. above this price for delivery in New York. No change was heard in producers' views for future contracts and 15c. seemed to be the prevailing quotation. Resale solid *caustic soda* was held at \$3.75 per 100 lb. on spot in most resale quarters. Occasional sales were noted at \$3.65@\$3.70 per 100 lb. and outside makes were reported obtainable at 3½c. per lb. Demand for additional lots for shipment continued rather quiet. Producers' ideas were unaltered for future contracts and the market was quoted firm at 3½c. per lb. basis 60 per cent works, for delivery over 1921.

Cyanide of soda was the most active chemical on the entire list during the past week. A noted increase in orders and inquiries was reported for the imported material. It was stated that several large orders were received from automobile manufacturers. Round lots were scarce and the market displayed a distinctly firmer tendency. Small quantities of the American grade were quoted at 28@30c. per lb., the outside figure being the producers' standard price. The German variety for shipment was quoted at 18½@20c. per lb., according to quantity and seller. Spot material was quoted at 24c. per lb. Producers are not inclined to shade 8c. per lb. on concentrated *sulphide of soda*, 60-62 per cent, in drums, for spot material. Dealers are in possession of moderate quantities of stock intended originally for export which they are offering at 7@7½c. per lb. Sales on *formaldehyde* were reported at 18½c. per lb. in bbl. by dealers and the general quotation was from 18½c. to 19c. per lb., depending on quantity. In some second-hand quarters it was stated that a few small lots might be purchased a shade under the inside figure, although it was admitted that the undertone of the general market was firm. Inquiries were said to be reaching the market from both domestic and export sources.

Odd lots of *oxalic acid* were on the market at 18c. per lb. Dealers stated that it was doubtful if much prime stock could be purchased below 18½c. per lb., while leading sellers were holding the market at 20c. per lb. The recent advance in this chemical has not met with the approval of buyers and trading continued along very quiet lines. Prime American *sulphate of aluminum*, iron free, was offered on the open market at 4c. per lb. f.o.b. New York. Imported material was available down to 3½c. per lb. and possibly a shade under this figure. The commercial grade was quoted at 2½@2½c. per lb., with most sellers asking the outside price. Producers reported a well-sold-up condition, but there seems to be relatively little activity in the open market at present. Increased inquiries on *prussiate of soda* were noted during the week, and a fair amount of business was reported to have been placed on the basis of 17½c. per lb. Offerings were not heavy and the tone of the market appeared quite firm. At the close, 17½@18½c. per lb. was the prevailing quotation.

Light *soda ash* for future shipment is being booked by the consuming trade at \$1.82½@\$1.90 per 100 lb., basis 48 per cent, f.o.b. works, in single bags. Inquiries were said to be reaching the market in better volume than noted earlier in the month. According to the views of dealers, there is not much resale stock pressing at the present time. The market was quoted at \$1.90@\$1.95 per 100 lb. in bags, while barrels

were held as high as \$2.10 per 100 lb. At the works occasional lots brought \$1.70@1.75 per 100 lb. in single bags.

COAL-TAR PRODUCTS

According to all advices, trading in coal-tar products was meager during the past week and prices in many cases were merely nominal. Consumers in all branches of the allied trades are holding off on account of uncertainty as to how far prices may be lowered. This is reflected in the coal-tar industry. Furthermore, if legislation on protective measures now before Congress is too long delayed, the market will reflect a serious uncertainty.

The crude market is in an easy position at present on supplies, and producers feel that there is a real demand and the time is not far off when it must be noticed. Intermediates in second hands still show irregular price levels with the tendency toward weakness. There is nothing radically new to report in the color market, except that considerable hard work is being put in on the dye protective measure and some interests feel very sanguine of favorable results. Supplies in second hands, while easy, are not being pushed to the extent they were a few weeks ago, and those that can afford to hold have determined not to take a conservative course in offering out supplies.

A rather stagnant condition is accorded to *cresol*, while makers report fair supplies ranging in prices from 16c. to 18c. per lb. Factors reported a moderate movement in *cresylic acid* against standing orders, but said there was very little new business coming through. Supplies were easy with continued shipments from abroad and prices ranged from 90c. to \$1 per gal. for the 95-97 per cent, and \$1@1.05 per gal. for the 97-99 per cent. There have been no new developments of late that would signify any increase in the consuming demand for *metaphenylenediamine* and only small lots were said to be moving. Prices remained quothably unchanged at \$1.25@1.30 per lb. Reports on *puratoluidine* from most quarters showed very little new business and only small lots moving against standing orders. Supplies were available in fair volume at \$1.75@1.85 per lb. Buyers are only taking very limited quantities of *paranitraniline* at this period. Supplies were plentiful in most quarters and prices ranged from 92c. to \$1 per lb., according to quantity and seller. *Beta naphthol* prices have halted in their downward course and seemed to be more uniform around 40@43c. per lb. *Phenol* has strengthened somewhat, with prices around 10@12c. per lb., none of the low quotations recently heard being in evidence.

Denatured Alcohol Production

All distilleries and industrial distilleries producing alcohol were required to requalify as industrial alcohol plants when the national prohibition act became effective, according to a recent report of the Commissioner of Internal Revenue for 1920. On June 30, 1920, there were thirty-seven industrial alcohol plants, compared with forty-seven distilleries operating prior to October, 1919.

At the close of the fiscal year 1919 there were forty-seven distilleries operating. There were in operation June 30, 1920, twenty-four denaturing plants, compared with forty-five denaturing warehouses and one redenaturing plant operated at the close of the fiscal year 1919. The number of bonded manufacturers using specially denatured alcohol increased during the fiscal year 1919, indicating an increased use of industrial alcohol.

During the fiscal year ended June 30, 1920, there was produced from materials other than fruit 99,615,792 taxable gallons of distilled spirits, an increase of 639,673 gallons compared with the quantity produced during the preceding fiscal year. Of this class of spirits there was removed from bonded warehouses on payment of tax 28,220,909 taxable gallons, a decrease of 53,377,176 from the quantity taxed during the preceding fiscal year, due to the prohibition laws which prevented the use of such spirits for beverage purposes. Herewith are shown the quantities of distilled spirits produced, withdrawn and remaining in bond during the fiscal years 1910, 1915 and 1920.

In 1910: Produced, 156,237,526.4 gal; withdrawn, 126,384,726.7; in warehouse, 233,508,674.6.

In 1915: Produced, 132,134,152.2; withdrawn, 121,498,325; in warehouse, 253,668,341.3.

In 1920: Produced, 99,615,792; withdrawn, 28,220,909.6; in warehouse, 55,863,745.2.

During the fiscal year 1920 there was withdrawn from bond, free of tax, for denaturation, 45,640,948 gal. of alcohol and rum, as against 60,399,308 withdrawn for the same purpose the previous year. The growth of the denaturing industry in this country during the past 14 years is shown by the following data beginning with 1907:

In 1907: Eight denaturing warehouses, producing 397,861.16 wine gallons of completely denatured alcohol and 382,415.19 wine gallons of specially denatured, a total of 3,084,950.8 proof gallons.

In 1910: Twelve denaturing warehouses, producing 3,076,924.55 wine gallons of completely denatured alcohol and 3,002,102.55 wine gallons of specially denatured, a total of 10,605,870.7 proof gallons.

In 1915: Twenty-three denaturing warehouses, producing 5,386,646.96 wine gallons of completely denatured alcohol and 3,002,102.55 wine gallons of specially denatured, a total of 25,411,718.1 proof gallons.

In 1920: Fifty-two denaturing warehouses producing 13,528,402.99 wine gallons of completely denatured alcohol and 15,307,947.18 wine gallons of specially denatured, a total of 45,640,948.6 proof gallons.

While the 1920 total is much larger than for 1915, there was a reduction from last year's total of about 15,000,000 proof gallons. Total proof gallons for 1919 were 60,399,308.9.

The Iron and Steel Market

Pittsburgh, Dec. 17, 1920.

Changes in market prices in the iron and steel industry in the past week have been few and unimportant. Tin plate, bars, shapes, plates, wire products and sheets, in all of which the independent market recently dropped to the Steel Corporation level, have undergone no further change. Shading by some of the independents is expected, but this has not been observed as yet, partly no doubt because the situation is so new and partly also without doubt because there has been little if any business offered that would induce price competition. Already some members of the trade have picked out some producers as being most likely to shade prices eventually and others who are at least likely to do so.

Pipe, in which the independent market did not decline to the Steel Corporation or Industrial Board level when so many other products did, is unchanged in the independent market, but in the past week there have suddenly appeared a great many postponements of deliveries against contracts, with a few cancellations, and the independents will probably soon have occasion to replace their 54 per cent list with the 57½ per cent list the Steel Corporation has maintained. The difference is about \$7 per net ton. Delivery premiums that were formerly obtained by independents have disappeared recently.

OPERATIONS

The altogether unprecedented performance of the Steel Corporation maintaining a certain set of prices and all the independents obtaining for a long time not only higher prices but in many cases very much higher prices would naturally have an aftermath, and that is now being experienced. The United States Steel Corporation has increased its rate of production, while the production rate of the independents is rapidly decreasing. The Steel Corporation's increase is not on account of its having more orders or being under greater pressure for deliveries, but because better transportation conditions have increased its supplies of coal and coke. A number of blast furnaces, long idle perforce, have lately been blown in. The corporation's rate of ingot production is now about 91 per cent of capacity, against 88 per cent two or three weeks ago. Some independents are down entirely, while others are operating at 50 to 75 per cent. The average independent rate is probably under 40 per cent and it is a common view that by the end of the year many independents will be closed entirely. The Steel Corporation's steel ingot capacity, as indicated

by the last annual report, is about 23,000,000 tons per annum. The total capacity of the country may be taken at about 52,500,000 tons, which would set the independents at 29,500,000 tons. At 91 per cent the Steel Corporation would be making ingots at the rate of 21,000,000 tons per annum. The average production rate during the first ten months of this year was 42,000,000 tons, with only minor variations from the average for a month or two at a time. Consumption did not exceed the production rate, as there were no stocks Jan. 1, and there may have been some stocks Nov. 1. Thus the steel required from independents is only the amount by which consumption exceeds one-half the consumption during the period in which consumption was regarded as very heavy and steel was very scarce. If consumption is reduced by one-third, there is left a rate of 7,000,000 tons a year for the independents, or 24 per cent of capacity. This seems remarkable, but it appears less so when it is considered, first, that on account of various difficulties the steel industry operated at only about 80 per cent of capacity in the first ten months of this year and second, that after the very remarkable price performances of the past twelve months the relative positions of the Steel Corporation and independents could not possibly become normal in any short space of time.

SEMI-FINISHED STEEL

"A large independent interest which has been particularly right in efforts to maintain prices has revised its sheet bar contracts to \$47, which is commonly recognized as the Steel Corporation price. Other mills are understood to be willing to sell sheet bars at this price, but there is no demand. Some sheet mills insist that the Steel Corporation's advance from \$42 to \$47 last September must be regarded as merely temporary and they are therefore indisposed to buy at above \$42, particularly since that is the Industrial Board price and the sheet market is now at Industrial Board prices. Billets are altogether indeterminate, there being no demand. Some slabs have been sold by plate mills at special prices.

PIG IRON AND COKE

Resale foundry iron has been offered so freely at \$35 valley basis or less and has met with so little sale that the market is easily quotable at not over \$35, the last regular furnace quotation having been \$37. Bessemer remains quotable at \$35 valley, and basic at \$33. Prices are practically nominal. The appearance of important inquiry would doubtless bring out competitive and therefore lower prices, but the demand does not appear. Part of the decline to date from the top prices reached last August has been more or less by way of voluntary action on the part of furnaces, but there is no disposition to go farther in that spirit. The lowest prices for pig iron on this decline will probably be developed after a regular buying movement has begun, whenever that may be, not when, as at present, furnaces are facing the prospect of going out of blast but rather when idle furnaces are thinking of getting into blast and are therefore desirous of selling some "backlog" tonnage for a start.

The average furnaceman is indisposed to consider the making of coke contracts for the first half of the new year, even though these contracts are by trade custom "requirement" contracts, so that the furnaceman is under no obligation if his stack is out. Furnacemen think developments of the near future will reduce Connellsville coke operators to lower terms than they are disposed to consider at present, while as a rule they see no definite prospect of having occasion to operate. This week an exception is to be recorded, however, as one coke interest has closed contracts with merchant furnaces involving coke equal to about 80 per cent of its capacity, or sufficient for four or five medium sized stacks. These contracts were all written on the general basis of a 5 to 1 ratio against basic pig iron, valley, the invoice price of the coke each month per net ton at ovens to be one-fifth the quoted market price of valley basic iron. That would be \$6.60 if pig iron stayed at its present level. The contracts contain a minimum for coke, also a change to a stiffer ratio in case pig iron should reach a certain level above the present price.

Talc, roofing grades, f.o.b. Vermont.....	ton	9.50	—	15.00
Talc, rubber grades, f.o.b. Vermont.....	ton	12.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	12.00	—	15.00
Talc, imported.....	ton	60.00	—	70.00
Talc, California Talcum Powder grade.....	ton	20.00	—	45.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	1,000	160	—	160
Chrome brick, f.o.b. Eastern shipping points.....	net ton	100-110	—	110
Chrome cement, 40-45% Cr ₂ O ₃	net ton	55-60	—	60
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points.....	net ton	60-65	—	65
Fire clay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	55	—	60
Fire clay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	45-50	—	50
Magnesite brick, 9-in. straight.....	net ton	110	—	110
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	121	—	121
Magnesite brick, soap and splits.....	net ton	134	—	134
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	65-70	—	70
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	56-61	—	61
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	55-60	—	60

Ferro-Alloys

All f.o.b. Works

Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—	\$225.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon, carlots.....	lb.	16	—	17
Ferro-chrome, per lb. of Cr. contained, 4-6% carbon, carlots.....	lb.	17	—	18
Ferro-manganese, 76-84% Mn, domestic.....	gross ton	140.00	—	145.00
Ferro-manganese, 76-80% Mn, English.....	gross ton	135.00	—	140.00
Spiegel Eisen, 18-22% Mn.....	gross ton	60.00	—	65.00
Ferro-molybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.00	—	2.50
Ferro-nickel, 10-15%.....	gross ton	60.00	—	65.00
Ferro-nickel, 50%.....	gross ton	78.00	—	80.00
Ferro-nickel, 75%.....	gross ton	100.00	—	100.00
Ferro-tungsten, 70-80%, per lb. of contained W.....	lb.	.65	—	.75
Ferro-uranium, 35-50% of U, per lb. of U content.....	lb.	7.00	—	7.50
Ferro-vanadium, 30-40% per lb. of contained V.....	lb.	6.50	—	7.50

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al, content, less than 2% Fe ₂ O ₃ , up to 20% silica, not more than H ₂ O moisture.....	gross ton	\$10.00	—	\$11.00
Chrome ore, Calif. concentrates, 50% min.....	unit	.60	—	.65
Chrome ore, 50% Cr ₂ O ₃ , f.o.b. Atlantic Seaboard.....	unit	.60	—	.65
Coke, foundry, f.o.b. ovens.....	net ton	8.50	—	9.00
Coke, furnace, f.o.b. ovens.....	net ton	7.00	—	7.50
Coke, petroleum, refinery, Atlantic Seaboard.....	net ton	24.00	—	26.00
Fluor spar, lump, f.o.b. Tonuco, New Mexico.....	net ton	17.50	—	17.50
Fluor spar, standard, domestic washed gravel Kentucky and Illinois mines.....	net ton	22.50	—	25.00
Ilmenite, 52% TiO ₂ , per lb. ore.....	lb.	.01	—	.01
Manganese Ore, 50% Mn, c.i.f. Atlantic seaport.....	unit	.45	—	.50
Manganese ore, chemical (MnO ₂).....	gross ton	60.00	—	65.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂ , N. Y.....	lb.	.55	—	.60
Monazite, per unit of ThO ₂ , c.i.f. Atlantic seaport.....	unit	35.00	—	35.00
Pyrites, Spanish, fines, c.i.f. Atlantic seaport.....	unit	.12	—	.12
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport.....	unit	.17	—	.17
Pyrites, domestic, fines, f.o.b. mines, Ga.....	unit	.12	—	.14
Rutile, 95% TiO ₂ , per lb. ore.....	lb.	.15	—	.15
Tungsten, Scheelite, 60% WO ₃ and over, per unit of WO ₃ (nominal).....	unit	4.25	—	4.50
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃ , N. Y. C.....	unit	4.00	—	4.25
Uranium Ore (Carnotite) per lb. of U ₃ O ₈	lb.	2.75	—	3.00
Uranium oxide, 96% per lb. contained U ₃ O ₈	lb.	2.75	—	3.00
Vanadium pentoxide, 99%.....	lb.	12.00	—	14.00
Vanadium Ore, per lb. of V ₂ O ₅ contained.....	lb.	1.50	—	1.50
Zircon, washed, iron free.....	lb.	.05	—	.05

Non-Ferrous Metals

New York Markets

	Cents per Lb
Copper, electrolytic.....	15.00
Aluminum, 98 to 99 per cent.....	22.00 to 33.00
Antimony, wholesale lots, Chinese and Japanese.....	5.62
Nickel, ordinary (ingot).....	43.00
Nickel, electrolytic.....	45.00
Tin, 5-ton lots.....	35.25
Lead, New York, spot.....	5.75
Lead, E. St. Louis, spot.....	6.25
Zinc, spot, New York.....	7.00
Zinc, spot, E. St. Louis.....	6.75

OTHER METALS

Silver (commercial).....	oz.	—	—	—
Cadmium.....	lb.	\$1.40	—	1.50

Soft steel bands.....	4.65	5.50	4.07	6.25
Plates, 1/2 to 1 in. thick.....	4.00	4.15	3.67	3.78

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

BURBANK—The Linoleum & Window Shade Co. is having plans prepared for the construction of three buildings on Vine St. and San Fernando Rd., to include a 42x201-ft. main building, 25x25-ft. warehouse and a 20x30-ft. office building. Cost to exceed \$50,000.

Connecticut

WEST HAVEN (New Haven P. O.)—The Tidewater Oil Corp., Wood St., will build an oil plant to include a 1½-story, 40x100-ft. oil warehouse and storage building and a 1-story, 40x50-ft. garage. Estimated cost, \$25,000. Work will be done by day labor.

Idaho

WEISER—The city plans an election Jan. 4 to vote on \$150,000 bonds to build a water system, including a filtration plant. L. C. Kelsey, filler, engr.

Illinois

BLOOMINGTON—The city will receive bids in January for the construction of a sewage disposal plant. Estimated cost, \$60,000. Alvord & Burdick, 8 South Dearborn St., Chicago, archts.

CHICAGO—A. M. Castle & Co., 715 North Morgan St., plans to construct an additional warehouse to have 150,000 sq. ft. of floor space. Estimated cost, \$450,000.

Indiana

EVANSVILLE—The Evansville College will receive bids until Jan. 15 for the construction of a 3-story, 70x120-ft. science hall. Estimated cost, \$250,000. Miller, Pullenwider & Dowling, 6 North Michigan Blvd., Chicago, Ill., archts.

ELINT—D. O. Oury, Trustee, Angola, will receive bids in January for the construction of a 2-story, 80x80-ft. school. A sewage disposal plant will be installed in same. Estimated cost, \$75,000. A. H. Ellwood & Son, Elkhart, archts.

GARY—The American Pure Paint Co. is building a 40x100-ft. plant for the manufacture of paint pigment and putty. Estimated cost, \$30,000. W. J. Schroeder, secy.

Iowa

SIOUX CITY—The Zonta Tire & Rubber Co. has awarded the contract for the construction of a 1-story, 100x120-ft. factory, to the Federation Constr. Co.

Louisiana

BASTRUP—L. H. Fox has awarded the contract for the construction of a reduction plant to include three 2-story, 50x200-ft. buildings and four 1-story, 30x60-ft. buildings, to the Widmer Eng. Co., Century Bldg., St. Louis, Mo. Estimated cost, \$200,000.

Maine

ROCKLAND—The Rockland & Rockport Lime Co. will build an addition to its lime plant, to include 6 limekilns and gas producers, 1-story, 35x100-ft. main building and a 2-story, 60x108-ft. lime storage and packing house.

Massachusetts

AMHERST—The Massachusetts Agricultural College plans to build a laboratory building. Estimated cost, \$200,000.

Michigan

HOLLAND—The city is having plans prepared for the construction of a sewage treatment plant. Estimated cost, \$200,000. Greeley, Pearce & Hausen, 39 West Adams St., Chicago, Ill., archts.

RIVER ROUGE—The Bd. Educ., c/o A. R. Heuer, has awarded the contract for the construction of a 3-story high school on Dearborn Rd., to Bryant & Detwyler.

2336 Dime Bank Bldg., Detroit. A chemical laboratory will be installed in same. Estimated cost, \$1,000,000. Noted Nov. 17.

Minnesota

BELLINGHAM—The Bd. Educ. is having plans prepared for the construction of a 2-story, 50x140-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$80,000. J. L. Mittelstadt, clk.

NEW PRAGUE—The Bd. Educ. plans to build a 2-story high school. A chemical laboratory will be installed in same. Estimated cost, \$85,000. J. Joach, clk.

OWATONNA—The city plans an election Jan. 10 to vote on \$475,000 bonds to construct a gas plant, etc. C. J. Servatius, city clk.

SHERBURN—The Bd. Educ. plans to build a 2-story high school. A chemical laboratory will be installed in same. Estimated cost, \$85,000. J. Schott, clk.

Missouri

MAPLEWOOD (St. Louis P. O.)—The St. Louis Paper Can & Tube Co., 4400 North Union Ave., St. Louis, has awarded the contract for the construction of a 1-story, 200x540-ft. factory on Big Bend Rd. along the tracks of the Missouri Pacific R.R., to the Widmer Eng. Co., Century Bldg., St. Louis. Estimated cost, \$500,000.

North Carolina

MAIDEN—The town has awarded the contract for the construction of 3 sewage disposal plants, etc., to Boyd, Higgins & Co., forth, Charlotte. Estimated cost, \$115,000.

North Dakota

CARRINGTON—The Bd. Educ. is having plans prepared for the construction of a 2-story high school. A chemical laboratory will be installed in same. Estimated cost, \$150,000. E. T. Smith, Supt. Shannon, Boyd & Boyd, Jamestown, archts.

CARRINGTON—C. C. Carnahan, city clk., will receive bids in the spring for the construction of a sewage disposal plant. Estimated cost, \$15,000. L. P. Wolff, 1000 Guardian Life Bldg., St. Paul, engr.

Ohio

PAINESVILLE—The Middle States Rubber Co., c/o E. Ewing, 708 Williamson Bldg., is having plans prepared for the construction of a 2-story, 60x200-ft. factory and warehouse. Estimated cost, \$200,000. Osborn Eng. Co., 2848 Prospect Ave., archt. and engr.

PORTSMOUTH—The Bd. Educ. plans to build a 3-story, 110x130-ft. high school. Laboratory equipment will be installed in same. Estimated cost, \$400,000. A. Pretzinger, 1155 Reibold Bldg., Dayton, archt.

Pennsylvania

CHARLEROI—The Federal Fdry. Supply Co., 2633 East 79th St., Cleveland, O., plans to build a 2-story, 40x92-ft. factory. Estimated cost, \$30,000. J. Bayer, pres.

South Dakota

WATERTOWN—The Bd. Educ. plans to build a 2- or 3-story high school. A chemical laboratory will be installed in same. Estimated cost, \$250,000. A. Herzog, clk.

Utah

SALT LAKE CITY—The School Bd. will soon award the contract for the construction of a 2-story, 68x218-ft. junior high school. Science rooms and chemical equipment will be installed in same. Estimated cost, \$250,000. F. D. Rutherford, 662 Second Ave., archt. and engr.

Virginia

EMPORIA—The Emporia Potassium Phosphate Co. plans to build a fertilizer plant. Carnel & Johnston, Chamber of Commerce Bldg., Richmond, archts.

Wisconsin

CHIPPEWA FALLS—The Bd. Educ. will receive bids about Feb. 1 for the construction of a 2-story, 125x160-ft. addition to

the junior vocational school. A chemical laboratory will be installed in same. Estimated cost, \$150,000. Beers, Schlitz & Bailey, engrs.

JANESVILLE—The Bd. Educ. will receive bids in the spring for the superstructure of a 3-story, 180x200-ft. high school, etc. A chemical laboratory will be installed in same. Estimated cost, \$500,000. Van Ryn & DeGijke, Caswell Bldg., Milwaukee, archts. Noted Dec. 15.

Ontario

LONDON—The Bd. Educ., Hydro Offices, is having plans prepared for the construction of three 2-story, 100x220-ft. high school. Equipment for chemistry and physical laboratories will be installed in same. Estimated cost, \$750,000. L. E. Carrothers, Hydro Offices, archt.

Quebec

SOREL—M. J. Danneveau will receive bids in January for the construction of a pulp mill to have a daily capacity of 100 tons of pulp. Estimated cost, \$500,000.

New Publications

THE CHEMICAL FOUNDATION, New York City, has issued a booklet on the "Electrochemical and Electrometallurgical Patents," which are owned by them.

THE COOKING INDUSTRY OF THE PACIFIC NORTHWEST. By Joseph Daniels, Bull. 9, Univ. of Washington, Seattle, Wash., Engineering Experiment Station.

THE COMMITTEE ON BIBLIOGRAPHY of the Technical Association of the Pulp and Paper Industry desires to call the attention of the paper industry, and especially those interested in scientific and technical cellulose chemistry, to two new German periodicals which are devoted entirely to cellulose:

Zellulose-Chemie, Wissenschaft Beibl.

Der Papierfabrikant.

This periodical, which is issued as a supplement to *Der Papierfabrikant*, is edited by Emil Heuser of Darmstadt. Vol. 1, No. 1, appeared April 30, 1920. It appears at monthly intervals, each number containing from 8 to 12 pages. The scope of the magazine may be seen from the following contents of the first five numbers.

No. 1, April 30, 1920, Advances in Cellulose Chemistry, by Emil Heuser.

No. 2, May 28, 1920, Methylation of Cellulose, by Denham and Woodhouse. (Translation of articles appearing in the *Journal of the Chemical Society*, vol. 103, p. 1,735 (1913); vol. 105, p. 2,357 (1914).)

No. 3, June 18, 1920, Trimethyl Glucose From Cellulose, by Denham and Woodhouse. (Translation from the *Journal of the Chemical Society*, vol. 111, p. 214 (1917). The Estimation of Cellulose in Wood, by W. H. Dore. (Translated from *Paper*, vol. 26, No. 1, p. 10 (1920).)

No. 4, July 16, 1920, The Enrichment of "Kraftstroph," With Fungus Protein, by Pringsheim and Lichtenstein.

No. 5, Aug. 20, 1920, Preparation of Alcohol From Wood, by Emil Heuser. The Constitution of Cellulose; an abstract of the work of Hess, appearing in *Z. Elektrochem.*, 1920, p. 233.

In addition to the major articles, each number contains a number of abstracts of articles from other journals on the subject of cellulose.

Der Papierfabrikant is published by Otto Elsner, Berlin, S. 12, Germany.

Zellstoffchemische Abhandlungen.

This monthly magazine is edited by Carl G. Schwalbe of Eberswalde, and is published by Carl Hoffman, Berlin S.W. 11, Germany. The price of the first five numbers of 1920 is 20 marks.

The first number (June, 1920) contains an article by Rudolf Sieber on the determination of the calcium content of fresh sulphide liquors according to Feld-Sander; and also the first part of an article from the laboratory of Ost in Hanover on the acetylate decomposition products of cellulose, by R. Prosegl. The July number completes the article by Prosegl and contains in addition an article by Schwalbe and Ernst Becker on the chemical composition of mechanical wood pulp.

NEW BUREAU OF MINES PUBLICATIONS: Bull. 189, Bibliography of Petroleum and Allied Substances, 1917, by E. H. Burroughs; Bull. 184, The Manufacture of Sulphuric Acid in the United States, by A. E. Well and D. E. Fogg; Tech. Paper 259, Production of Explosives in the United States During the Calendar Year 1919, by William W. Adams.

U. S. TARIFF COMMISSION PUBLICATION: Industrial Readjustments of Certain Mineral Industries Affected by the War.

Coming Meetings and Events

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its 1920 meeting Dec. 27, 1920, to Jan. 1, 1921, at Chicago, Ill.

AMERICAN CERAMIC SOCIETY will hold its annual meeting the week of Feb. 21, 1921, at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29, 1921.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting Feb. 14 to 17 in New York City.

AMERICAN PHYSICAL SOCIETY will hold its annual meeting, beginning Dec. 28, at Chicago, it being the occasion of the special quadrennial meeting of the American Association for the Advancement of Science and the Affiliated Societies.

COMMON BRICK MANUFACTURERS' ASSOCIATION OF AMERICA will hold its annual meeting at the Hotel Pennsylvania, New York City, Jan. 31 to Feb. 4.

COMPRESSED GAS MANUFACTURERS' ASSOCIATION will hold its eighth annual meeting, Monday, Jan. 17, 1921, at 2 p.m., at the Hotel Astor, New York, and its eighth annual dinner at the same place that evening.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at the Statler Restaurant, Newark, N. J., the second Monday of every month.

SOCIETY OF CHEMICAL INDUSTRY holds its Perkin Medal Award Meeting at Rumford Hall, Chemists' Club, New York, on Jan. 14, 1921.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: Jan. 7, American Chemical Society; Jan. 14, Society of Chemical Industry, Perkin Medal award; Feb. 11, American Electrochemical Society, joint meeting with Society of Chemical Industry, American Chemical Society and Société de Chimie Industrielle; March 11, American Chemical Society, Nichols Medal award; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Industrial Notes

THE AMERICAN CHAMBER OF COMMERCE in London has just published its year book for 1920, containing the names, addresses and business classifications of over 1,000 American and British firms and individuals interested in developing business between the two countries. The book should be useful in connection with overseas trade and markets.

THE NASHVILLE INDUSTRIAL CORPORATION, composed of business men of Nashville, Tenn., has purchased from the U. S. Government the Old Hickory powder plant at Jacksonville, Tenn., located twelve miles east of Nashville, on the navigable Cumberland River. The purpose of the Nashville people is to industrially develop this immense war undertaking into a large manufacturing center, having available immense housing and manufacturing buildings and facilities. The village had a population of 35,000 when the plant was closed in 1918, and is now completely equipped with all necessary public utilities, schools, banks, clubhouses, etc., and offers many attractive inducements to new industries or those desiring a change in their location. This was the largest Government manufacturing undertaking during the war, costing over \$87,000,000. It occupies 5,100 acres of land, has a water filtration system capable of supplying a city the size of Boston, one of the largest steam power plants in the world, a double-track railroad connecting with trunk lines, thirty-five miles of industrial track connecting manufacturing buildings, an immense refrigeration system, complete water works, sewerage system, fire departments, concrete and macadam roads. A great quantity of surplus material in the manufacturing area will be dismantled and sold.

THE AMERICAN DRESSLER TUNNEL KILNS, INC., has removed its executive, engineering and thermal offices to 1740 East 12th St., Cleveland, O.

THE BARBER-GREENE CO., Aurora, Ill., has recently added to its sales force in St. Louis L. M. Dosier. Mr. Dosier was formerly with the Lakewood Engineering Co.

THE GORDON DRYER CORPORATION, maker of Gordon Atmospheric Dryers, has for more than a year been operated in affiliation with Grinnell Co., Providence, R. I., stock control of the Gordon Corp. having been passed to the Grinnell interests in March, 1919. Under the new management the company's business grew rapidly and increased manufacturing facilities were soon required to meet the demand for its products. To secure output it was decided to discontinue the Gordon factory at Bush Terminal, Brooklyn, and last April manufacturing operations were transferred to the Grinnell plant in Providence. The construction of a large plant is now being started in Warren, Ohio.

THE OHIO EXPORT & TRADING CO., with offices in the Standard Parts Bldg., Cleveland, and branch offices in New York and several European centers, has recently organized a department dealing with export and import of chemical machinery, heavy chemicals and miscellaneous finished and semi-finished materials.

AMERICAN STEAM CONVEYOR CORP., Chicago, announce that the J. B. Engineering Sales Co. has been appointed its Connecticut sales agent, with offices at 60 Prospect St., Hartford, Conn.

THE BARTHOLOMEY CO., INC., has let a contract for converting the Genesee Brewery, Rochester, N. Y., into a vegetable oil refinery, using the Brown-Baskerville process. The plant will have a capacity of 50 tons of oil a day. H. E. Brown, New York City, is the engineer.

GROSS, SON & ROBERTSHAW have been appointed sole selling agent for Wild-Barfield electric furnaces for the counties of Northumberland, Durham, Cumberland and Yorkshire. In addition to the office in Newcastle, England, the firm has opened a branch office at 41 Great George St., Leeds, England, where a demonstration furnace is in course of erection. Macbeth Bros. & Co., Ltd., of Bombay and Calcutta, have taken over the sole selling rights for India, where these plants are already in operation.

THE KEWANEE BOILER CO., Kewanee, Ill., held a large celebration on the event of the completion of its million-dollar plant addition on Oct. 20. Many speeches were made by the local city officials and members of the Chamber of Commerce.

THE CUTLER-HAMMER MFG. CO., of Milwaukee and New York, has recently acquired the property at 137th St. and Southern Boulevard, in New York City, as an additional plant for the manufacture of "Thermoplas" and "Pyroplas" molded insulation. The five-story building on this property has been completely equipped with presses for this work. When working at capacity the new plant will have an output equal to the company's insulation plant in Milwaukee, which has been running two shifts, night and day, for the past three years. The New York plant will take care of the company's Eastern business in this line, and will relieve the Milwaukee plant, which is overtaxed in supplying the demand for molded insulation parts. F. J. Boller, formerly of the Milwaukee insulation department, is in charge of the new plant.

FAIRBANKS, MORSE & CO., has purchased the entire business, consisting of all stock on hand, good-will and liabilities, of the Luster Machine Shop & Railway Equipment Co., 917 Arch St., Philadelphia, and has opened a new branch at this address under the management of D. W. Dunn, who will sell the company's complete line of engines, motors, pumps, etc. The entire personnel of the Luster Machinery Co. has been retained. E. J. Luster, former president, will be manager of the machine tool division of the Fairbanks-Morse Philadelphia branch.

CHICAGO BRIDGE & IRON WORKS, Chicago, Ill., announces the opening of a new sales office at Atlanta, Ga., in the Forsythe Bldg. Joseph L. Zeller, who has been with this company for a few years, will be in charge and have the territory including the states of Georgia, Alabama, Tennessee and Florida.

THE CEMENT GUN CO., INC., announces new Report on Tests of Gunite Slabs, which gives working tables and safe load tables, established through tests. The company also announces the removal of its main office from Allentown, Pa., to Cornwells, Bucks Co., Pa.

SAMUEL LEDEBER has purchased the plant of the Hammond Brewing Co., West Ham-

mond, Ill., which will be put into operation for the manufacture of beverages.

MORSE CHAIN CO., Ithaca, N. Y., has established a Detroit branch factory, which will be devoted exclusively to the manufacture of silent chain sprockets and the Morse adjustment. The Morse Chain Co. will continue to manufacture chains and power transmission at the main plant at Ithaca. The Detroit branch will be under the general management of F. C. Thompson, with F. M. Hawley as chief engineer and C. B. Mitchell as factory manager. Sales and engineering offices are located at the Detroit plant, corner of Eighth and Abbott Streets. The Detroit plant has been added to partly relieve the Ithaca plant. Since the first buildings were erected at Ithaca in 1907 this company has been continuously adding new buildings; in fact, there are now three large construction gangs at work on two large new concrete buildings, making considerable addition to the 7 acres of floor space now under roof as well as another concrete stack, 185 ft. high providing for additional power plant equipment. This company also announces that the Morse Chain Gang is always studying and looking for improved and more efficient machines, tools, and equipment, and would appreciate receiving the latest in catalogs, booklets and circulars.

THE CHICAGO PNEUMATIC TOOL CO. announces the removal of its rock drill plant from 864 East 72nd St., Cleveland, O., to the company's Boyer pneumatic hammer plant at 1301 Second Blvd., Detroit, Mich. Location of the company's Little Giant air drill plant at 1241 East 49th St., Cleveland, remains unchanged.

HUGO ZELLER announces that he has resigned as president, treasurer and general manager of the Egyptian Lacquer Mfg. Co., having offices at 5 East 40th St., New York City. Richard Zeller and Gustav Zeller, his brothers, who were also connected with the Egyptian Lacquer Mfg. Co. in the manufacturing end, occupying positions respectively of vice-president, secretary and plant managers and assistant secretary and assistant plant manager, have also resigned from this concern. The three brothers Zeller will continue to be identified together and announcement regarding their plans will be issued in the near future.

THE CHAIN BELT CO., Milwaukee, Wis., announces that Clifford E. Messinger has been appointed general sales manager to succeed L. C. Wilson, who has resigned to become secretary of the Federal Malleable Co., closely associated with the Chain Belt Co. Other promotions announced are C. E. Stone, assistant to the vice-president, and J. A. Monahan, purchasing agent. Mr. Messinger, for the last two years assistant to the vice-president, is a Yale graduate and has been connected with the Chain Belt Co. since 1911. He is perhaps best known in his capacity as manager of Rex Mixer Sales, which he held for three years, and has also been advertising manager. Recently Mr. Messinger has been elected chairman of a group of nationally known construction machinery manufacturers associated for the purpose of developing export business.

ALBERT H. HOPKINS has resigned from the presidency of the Engineering Advertisers' Association of Chicago and from the management of advertising and sales promotion departments of the C. F. Pease Co., Chicago, to become Chicago manager for the J. Roland Kay Co., international advertising agents, at their new building at 161 East Erie St., just east of North Michigan Boulevard. Mr. Hopkins is known through the Middle West as a former publishers' special representative and through his activities as an organizer and charter member of the above association. His association with the J. Roland Kay Co. will also be in the capacity of manager of its domestic division.

THE TEXAS PORTLAND CEMENT CO., Dallas, Tex., in line with the policy to keep its mills thoroughly modernized and to adequately provide cement for its trade, and which has recently doubled the capacity of its Houston mill, now announces that plans are prepared and work has actually started on the installation at its Dallas mill of one 9x200-ft. kiln, together with additional raw mill machinery and other construction necessary for the increased output.

E. F. HOUGHTON & CO., Philadelphia, announce that George H. Morgan has been elected treasurer. The position of secretary, formerly held by Mr. Morgan, has been filled by the election by the board of directors of George W. Prossell, chief of the Houghton research staff. Mr. Morgan will retain the position of managing director of the leather manufacturing department.

A Lagging Public Conscience

THE other day we saw an advertisement of one of the most popular magazines which has a large circulation among intelligent and thinking people. In what follows we do not criticize its editorial policy; indeed when we find ourselves quoted in its columns we admit frankly that we like it. What disturbs us is that in looking for opinions as expressed in American journals and periodicals it evidently has missed something, and the reason is because what we have in mind isn't there. The advertisement reads, "If we join the League of Nations will it glorify us or destroy us? Shall we be able to 'readjust the affairs of civilization' or shall we 'surrender the republic'? Will (*sic*) we be safer in or out? Read both sides of the great national debate in . . ."

There we are! Shall we be glorified or injured or become the boss of all civilization or lose power, and how can we play for safety? How can we beat the game? Where does our advantage lie?

As a member of the great family of nations, if that is the substance of our interest, it indicates that we must be rather a mean brother. Or if we are a great business organization, it might almost be taken as a warning to look out for us. Every question has to do with jockeying for position, and not one touches our obligations or shows even an interest in how the other fellow is to live.

Now that does not represent the heart of the United States. It does not indicate the outcome of the Spanish war, the freedom of Cuba, or the intent of effort with Filipinos or Porto Ricans, irrespective of whether we have been successful in these efforts or not. We have no opinion to impose on our readers concerning the League of Nations; indeed a vote of our editorial staff would very likely show a considerable division of opinion on the subject, and we do not set up to be wise in the matter. International politics is not our *métier*. We merely claim that there is such a thing as a public conscience in this country. When we entered the great war we did so with a will, and we gave our best for a great human purpose and with no intent or thought of any gain at all. The fat profiteer at home does not detract from the glory of the silent heroes buried in France. The ideals were present among those who died and among those who fought and struggled and lived. The trouble is that having done a big and great thing we have called a halt, and that halt has entered into our souls. It almost seems as though, during the past two years, we had closed our minds to all consciousness of our obligations. We miss the idea in our newspapers, in our talk, in the air.

Now our obligations loom big, bigger than ever before. We hold a strategic position on the earth, we have the richest land and the advantage of long experience in self-

government. This indicates intelligence among our people. But all this will not keep us complacent and warm and rich unless we make ourselves desired for what we are just as much as if not more than for what we have to spend or to sell. Every business man knows the value of a good name and that good names are not achieved by astute jockeying for position or by trickery of any kind. Of course we must take care of our own, and of course we have immense duties at home and with our own people. We are not pressing any specific reform in this discourse; we are merely noting the absence of even the semblance of thought about our obligations, anywhere. The splendid magazine to which we refer is not to blame for this, even though the editor may have given the advertising man a little too loose a rein. What the editor found in comment was doubtless correctly set forth. What he did not find is that consciousness of what we owe to one another and to all men which it were better for us to consider. We need to do this thing by way of insurance for the next generation.

What to Do With The Patent Office Bill

IT IS EXCEPTIONAL, if not unprecedented, for a conference committee of the Senate and House of Representatives to re-open public hearings on a bill referred to it for final consideration. Accordingly it is a matter of gratification to all concerned that plans have been perfected for hearings on the Nolan Patent Office bill, to which the Senate has attached a rider providing for patenting the inventions of Government employees and administration of such patents by the Federal Trade Commission. These hearings will be held January 5, so we are informed.

Two things should be urged upon the conference committee: First, the bill should be relieved of its rider relating to patenting the inventions of Government employees; and second, the provisions of the House of Representatives for enlarging the examining and clerical forces of the Patent Office, and increasing their salaries, should be sustained as against the reductions recommended by the Senate.

The Nolan bill should be relieved of its rider because the two things have nothing in common except that they relate to patents. The bill has to do with administrative conditions in the Patent Office, on which there is unanimity of opinion, while the rider relates to a question of policy on which there is a marked difference of opinion between representatives of industry and the Government. There can be no possible excuse for confusing the two ideas or combining them for legislative purposes.

The salaries of examiners and clerks in the Patent Office should be greatly increased and made commensurate with the technical ability required of incumbents of those positions. It was in 1848, we believe, that the

salaries of chief examiners and Congressmen were identical. Since that time Congress has not forgotten to increase the salaries of its members several hundred per cent but has been curiously neglectful of the Patent Office, recognizing its employees with only minor increases in salary. As it exists today the condition in the Patent Office is a discredit to Congress, as well as a cause of dissatisfaction to industry, and should be remedied immediately.

Economic Lessons From Other Countries

RECOGNIZING the truism that necessity is the mother of invention, we of the United States have good reason to study what is being done in other countries where the pinch of necessity is forcing intelligent and vigorous action. Unless or until we all recognize that the people of the United States were spoiled by the war we shall get nowhere. In February, 1916, Sir GEORGE PAISH in an elaborate article in the *New York Sun* said:

"The idea that the United States is deriving or can derive any advantage whatever from the war is a complete delusion. All that is happening to the advantage of your country is that it is suffering less than the belligerents as a result of this titanic conflict."

Since we afterward entered the war, we lost, according to Sir GEORGE'S philosophy, the advantage we enjoyed as non-combatants. It may be that the statement is not strictly true, but there is something in it—more than we have thus far recognized.

A common delusion has been that inasmuch as the war interrupted certain kinds of progress we fell just that far behind, and that hence we should be the better off afterward because we would make progress more rapidly so as to catch up. If such a thing could be done, why didn't we just resolve unanimously a quarter century ago to double our rate of progress and then go ahead and do it?

We are now under the necessity of doing harder and more efficient work or of suffering the consequences; but, being spoiled, we do not yet recognize the fact. It is quite appropriate, then, to consider what other countries, under necessity, have done and are doing. After the Franco-Prussian war all France turned in and worked like a beaver to earn and pay the indemnity. France became highly prosperous. Germany, receiving the indemnity, became slothful and extravagant. The condition was so marked that a German comic paper a few years after the war exclaimed: "Let us have another war; let us be beaten and pay an indemnity and then we shall be prosperous again."

Many a true word is spoken in jest. Is that utterance of nearly a half century ago to prove prophetic? It is not as to France, for France is working, hard and intelligently. The French realize how much they lost, even though they won the war. Probably they would not be spoiled in any event, but they are not receiving the indemnity fast enough to put them in any danger. We need to take a lesson from France, for we are not as much better off as we think.

Now as to Germany, our latest advice from our Berlin correspondent tells of the progress the Stinnes movement is making in the German coal industry. In the Essen field an understanding has been reached on the Stinnes basis and the idea is spreading. The basis is far removed from Marxian socialism, which it is down-

ing so far at least as concerns the coal industry. Our correspondent says of it: "Socialization, as is now proclaimed, can be nothing else than a process for obtaining the most complete and economical utilization of all industrial products in the interest of the whole nation, whereby all classes taking part in the production should have a share in the control and in the responsibility." No change from existing conditions is to be tolerated except it promises improvement along this line. Ownership in the mines is unchanged, but workers are given opportunity to buy stock. Trusts as hitherto known are abolished. Production is to be increased, the existing mines being worked more intensively, instead of new shafts being sunk, strong and weak mines being joined to provide capital for improvement.

The operators and miners are to join hands, on the principle of "the interest of the whole nation." In the United States we have seen grounds for suspecting the operators and miners agreeing with each other too readily, with shortage of coal and high prices coming next, and the "percentage of operation" of the mines computed by dividing the number of hours in a day worked by eight, which is one-third of the twenty-four hours during which the capital involved is expected to draw interest and profits. Recently there have been some disclosures as to the building industry in New York where a curious mutuality of interest was shown to exist between labor unions and their employers.

We delude ourselves into thinking that we can afford to do these things, to be unintelligent and lazy and to exploit one another, that only the countries that are in a bad way need to work hard and efficiently. But we did lose by the war and we had better recognize the fact. Sir GEORGE PAISH "said something."

British Progress In Chemistry

REAL discourses for the guidance of the chemist are far from plentiful. Elsewhere in this issue will be found Mr. MACNAB'S thoughtful introduction to the Ministry of Munitions' publication "Preliminary Studies for H. M. Factory, Gretna," which is a true sermon for chemists and chemical engineers everywhere. If men of the profession are to assume the higher positions in industry they must secure experience in common-sense methods of procedure for construction and operation of plants, in things mechanical as well as chemical, in finance and organization. With such training, plus scientific education, they cannot fail to become the key-men in many industries now unaware of the benefits of technical control of operations.

Review of the book noted above will also be found in this issue. The methods of studying problems of plant design introduced by Mr. QUINAN as shown in the text have been the subject of favorable comment from several sources and hold the lesson of simplicity and clearness for technical procedure. QUINAN was a tower of strength to the British Ministry of Munitions. Not only was he forceful and vigorous in combating official ignorance and apathy, so that his plans and proposals were accepted, but he was unusually successful as a teacher in training the members of his technical staff. His final reports are models of excellence in portraying graphically the technical operations at various munition factories. Since Mr. QUINAN was a native American, we too may take some pride in his achievements for one of the Allies.

Arsine

Poisoning

A BRIEF statement in Mr. HANLEY's contribution on electrolytic cadmium, published on another page in this issue, warrants especial emphasis. He gives an alternative scheme for treatment whenever arsenic is present in the copper-cadmium-zinc precipitate to be placed in solution, so as to protect workmen from the "violently poisonous gas of reaction," arsine.

Many living chemists and electrometallurgists have had more or less close contact with this specter, and have almost instinctively closed their lungs to its disagreeable smell before inhaling a fatal amount—pure luck, which other men have not had. An amount as little as $\frac{1}{2}$ mg. of the gas has proved fatal to human beings, although more resistant persons have apparently absorbed as much as 8 mg. and yet recovered. Tests at the American University Experiment Station during the war showed that $\frac{1}{2}$ -hr. exposure to a concentration of 0.3 mg. arsine per liter of air is fatal to dogs. Mr. HANLEY is therefore correct in calling it a violent poison, a thing always to be safeguarded against.

Any electrolytic process liberating nascent hydrogen in solutions likely to contain arsenic, or on metal anodes containing arsenic, may under certain conditions as to acidity and concentration generate enough arsine to kill all the employees in that department. It is also formed whenever hydrogen is liberated in a solution containing arsenious acid or an arsenite. It will usually be liberated in quantity when acid acts on arsenic-bearing ores, residues or metals. Many electrolytic and solution processes which are potential arsine generators can readily be called to mind; it has been evolved in fatal quantities in tinning sheet iron, and in the solution of argentiferous zinc from Parkes process lead refining; it has killed lead-burners who used hydrogen from impure zinc.

Since the gas is nearly three times as heavy as air, dangerous concentrations may be reached within rooms, or even in the open air, unless all possible generators are covered and the hoods exhausted by fan suction, discharging preferably into a chimney, there to be highly diluted before again reaching the ground. Good ventilation is also necessary, and should be especially insisted upon in winter time, when the tendency of course is to shut the buildings tightly. Portions of a plant under suspicion should also be carefully walled off from adjacent departments, if it is not practicable to house them separately. Finally, the atmosphere from appropriate places should be tested by drawing a continuous stream of bubbles through an indicator like a silver nitrate solution, placed in a conspicuous position so that the darkening caused by traces of arsine will be immediately observed. Or one might devise a continuous Marsh test. Any arsenic mirror would absorb a portion of a beam of light falling upon a selenium cell, which through relays would then operate any electric alarm.

In view of the minute amount which causes death, attention of the responsible engineers should be focused on a careful study of the possibility that arsenic may accidentally or habitually enter an electrolytic or solution process. If it is impossible to eliminate this contingency absolutely, the process should be isolated, and the surroundings well ventilated and constantly tested.

Often the presence of arsine is unknown until its effect on the workmen's health is observed—then, perhaps, only too late! Would it not be well then to inquire

among the employees, whether they are at times subjected to unexplained attacks of tonsillitis or jaundice?

Symptoms of arsine poisoning are delayed—often as much as twelve or eighteen hours. One effect it takes, often in mild doses, is to cause partial or complete destruction of the mucous membranes in mouth and throat. The sufferer loses the sense of taste, finds it very hard to swallow, and is treated for "malignant tonsillitis." As a rule, however, the first symptoms are nausea, headache and giddiness, followed by jaundice of the skin and inner surface of the eyelids, the latter of which assumes an intense coppery hue. Its essential action is to destroy red blood corpuscles in enormous number, and the liver and kidneys ultimately break down in an effort to eliminate the products of disintegration. The duration of illness, whether fatal or not, is materially longer than that caused by other arsenicals. Eight days would be a minimum period of recovery—more than eight months is often required. Death may come within a day, or wait three or four weeks.

Facilitating Government Service to Industry

INDUSTRY has frequently resented Government efforts to investigate or assist in technical or commercial problems which industrial executives consider "none of the Government's business." Particularly this problem has confronted the technical man in cases where Government investigators working in chemical or engineering fields have striven to study specific industrial processes instead of confining their efforts to a study of fundamental problems common to all branches of one or more industries. Most recently vigorous objection has been raised on the score that the Government was seeking to influence patents, which in the opinion of many are distinctly commercial property.

There are two methods of preventing undue encroachment of public officials on subjects of concern to individual companies. One of these is purely a restrictive obstructionist policy by which the industry attempts to stop work that some Government specialist or executive happens to find interesting or believes to be properly subject to Government study. This policy always results in hostile feeling and very often defeats its own end, by making it appear that the industry has some unwarranted advantage it seeks to preserve.

Why not go to the Government with those problems which it can properly be asked to solve and which industry would like to have it study? Go with assurance that in most cases the Government worker and executive really wants to be of service. If convinced that the work suggested to him is useful and will be appreciated, the worker gladly will follow the desired channel of investigation and the only objection which industry will incur is to convince the legislative and appropriating agencies of the Government (that is, the Congressmen) that financial support should be given to these needed investigations. Once these investigations are properly explained and support of all proper sorts assured, the Government department will no longer show a desire to stray into those other lines which can best be studied by industry itself. Furthermore, the industry will thus obtain that effective Government work which it is entitled to expect from properly supported public agencies.

In other words, for the future when we deal with the Government investigations, let's boost what we do want, as well as knock what we don't want.

Western Chemical & Metallurgical Field

Novel Electrical Precipitator

At the Tooele plant of the International Smelting Co. a battery of thirty-two McDougall roasters discharge their smoke into a roomy dust-chamber immediately alongside, connected in turn to the main smelter chimney by a short stretch of brick flue. The dust chamber was designed to support Roesing wires, and these were installed but proved unsuccessful. A great deal of trouble was experienced with loose wires falling into the hoppers due to rapid corrosion near the point of support, the coolest portion. Consequently the wires were removed from the entire chamber.

After work with a small experimental plant, a so-called flue-type treater was installed, and has worked excellently, the recovery of values as indicated by filtration tests exceeding 90 per cent in all cases and at a remarkably low power input. Briefly, the installation consists of a short length of flue in which corrugated iron sheets are hung from the roof and set parallel to the flue-walls, to act as collecting electrodes. Discharge electrodes between plates are formed of gridirons of small iron pipe placed horizontally, and hung from supporting beams at the ends and middle point. Dusty gas thus passes through an electrified zone on its direct

toward the far end the dust runs sufficiently high in lead that its yieldings are sent to the lead blast-furnace plant.

Butterfly dampers, hinged both vertically and horizontally, control the gas distribution at both ends of this short flue; between are four sets of collecting electrodes extending from top of flue to top of hopper, and 10-ft. long. Between sets is left enough open flue to accommodate the discharge-electrode suspension. A particularly clever detail is illustrated in the accompanying sketch, where the electrode suspension passes into a dog-house covering high-tension insulators. A short length of wrought-iron pipe (machined smooth on the outside) is slipped over the I-beam, and this assembly passes the sheet-iron wall through a port-hole framed with a ring of 2-in. pipe. A minimum clearance (equivalent to sphere to plate conditions) prevents large leakage of outside air; any puffs of gas passing outwardly are cleared of dust particles by the charged field existing at the opening. In this manner the insulator is thoroughly protected from dust accumulations, and the treater is protected from a continual inrush of cold air.

Obscure circumstances led to a large overestimate of the electricity needed for operation. Preliminary experimentation indicated that about 50 kva. would be needed, while actually in operation not more than one-quarter of this amount can be put into the treater, this sufficing to catch eight or nine tons of dust daily.

From the description of the installation it may be observed that in effect the treater is really a series of four, each with a gas-travel of 10 ft. Between plate-banks considerable mixing occurs in the current and a solid particle enters the succeeding set at a position random to that at which it emerged. Yet considerable dust is caught on the last plates! Evidently, here is evidence contrary to the idea that a particle in a treater has a path the resultant of a translational velocity and an electrical impulse at right angles. Rather it is that a particle wanders along somewhat aimlessly until fortunately it becomes ionized, and then moves quickly to its oppositely-charged electrode.

Salines in Utah

The assessed valuation of non-metalliferous mining deposits in Utah for 1920 is \$22,686,748. The largest amount is for coal lands and totals \$19,091,647; sulphur deposits are assessed at \$22,530; lime quarries, \$31,943; cement rock deposits, \$1,372,755; salt and potash deposits, \$644,447; alunite deposits, \$274,477; asphalt deposits, \$1,062,764. These figures are for taxation purposes. In 1917 the assessed valuation of the above lands was \$11,012,926.

The potash deposits are in Piute County, and according to the estimate of Prof. William Peterson, geologist for the State Board of Equalization, there is a total of 643,000 tons of material that might be considered valuable for taxation purposes. The phosphate deposits are in Rich County, and consist of patented lode claims totalling 1,375 acres. Mr. Peterson estimates the tonnage assessable at 13,348,000. The gilsonite deposits in

DETAIL WHERE ELECTRODE SUSPENSION PASSES THROUGH SIDE WALLS

route from dust chamber to stack without suffering the usual twistings and turnings of the conventional Cottrell installation.

The flue itself is rectangular in cross-section, with steel top, transite sides, and steel-hopper bottom. Gas velocities approximate 20 ft. per second when twelve McDougall furnaces are operating, yet very high clearances are effected. There is also, curiously enough, a very definite selective action on the mixed smoke—the first hoppers collect material high in copper, while

Uintah County aggregate 3,490 acres, with an estimated tonnage of 3,438,500.

The Utah Salduro Co. has been granted a patent to 30,658 acres of land in the Great Salt Lake Desert, title to which was established under placer mining locations, made prior to the date of the leasing law. The company paid a fee of \$76,645. This entry covers probably the largest area ever patented under one mineral application. The company extracts potash salts from brine collected by means of dikes, ditches and canals covering a large area. Thus a section of the West heretofore considered so arid and alkaline as to be of absolutely no value is being made to supply a valuable commercial product. The potash industry in this region, however, is in a rather uncertain condition at the present time, owing to the fear of ruinous foreign competition.

A group of Chicago and Indiana capitalists have made application to the State Land Board for the lease of 640 acres of land for the development of potash, alunite and associate minerals. The section of land involved is east of Marysvale, in Piute County.

The Minerals Salt Co. has been recently incorporated with a capitalization of \$500,000. The company owns deposits of sodium sulphate on the south shore of the Great Salt Lake.

For some time past, the existence of sodium sulphate around the shores of the Great Salt Lake has been known, and the Midwest Dye & Chemical Co. has been producing glauber salt ($\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$) and salt cake at its plant about two miles southwest of the Garfield smelter. A chemical analysis of the sodium sulphate, made by Walter D. Bonner, head of the department of chemistry at the University of Utah, showed the following results:

	Per Cent
Sulphate, SO_4	63.87
Chloride, Cl	3.64
Magnesium, Mg	0.24
Calcium, Ca	0.36
Potassium, K	0.15
Sodium, Na	31.37
Total	99.63

Overlying the deposit, the extent of which has not been determined at either the south end or the north end of the lake, is 18 to 24 in. of sand, with some boulders. The overburden is easily removed, exposing the sodium sulphate, which is hard and crusty, and contains about 50 per cent sand. The deposit itself is from 5 to 7 ft. thick. After removing the sand overburden, live steam is injected into the deposit by means of an open-end pipe. The heat causes the salt to go into solution very rapidly, and practically all of the sand settles to the bottom of the deposit. When sufficient solution is accumulated, it is pumped into a small storage tank, where additional settling takes place. This solution is then decanted and stored in shallow evaporating ponds. As the solution cools, crystals of glauber salt form.

To Develop Sodium Sulphate Deposit

A deposit of anhydrous sodium sulphate has been purchased by Western Chemicals, Inc., of Tonopah, Nev., development of the deposit having located considerable quantities of 95 per cent sodium sulphate which can be removed by mining methods and put on the market as dug. The deposit is located about twenty-three miles south of Clarkdale, Ariz., to which place the material is now being hauled by truck.

Preliminary exploration indicates the deposit to be

quite large. Not all of the material is of a high degree of purity and it is the intention of the company to build a purification plant of sufficient size to supply any market demand which can be developed.

Canada Copper Corp. Reorganized

The Canada Copper Corporation, Ltd., has again been reorganized—the second time within the last few months. It will be recollected that the old company embarked about two years ago upon a rather ambitious development plan, which it was unable to carry entirely to completion, owing to the unfortunate incidence of high construction costs and low copper prices. Under more normal conditions operation of its 2,000-ton mill at Allenby would have doubtless been successfully under way some time ago.

New Process for the Treatment of Natural Brines

Shortly after the first of the year Wrinkle & Kuhnert, of San Francisco, will begin the operation of a demonstration plant at Keeler, Cal., for the recovery of potassium chloride and borax from Owens Lake's brines. The lake water will be evaporated to the maximum degree of concentration by solar evaporation, and the liquor freed from the mono- and bi-carbonate of soda by treatment with carbon dioxide. Further evaporation in double-effect evaporators will be followed by fractional crystallization. The process differs from others that have been tried in that the borax and potassium chloride are both recovered in a marketable form. The plant has a capacity of about twenty tons of sodium bicarbonate and about ten tons each of borax and potassium chloride.

Bituminous Sand Deposits, Athabasca Region

In the District of Fort McMurray, about 200 miles north of Edmonton, occur vast deposits of bituminous sands, popularly referred to as tar sands. The area of occurrence is vast, that indicated by exposures being estimated from 750 to 1,000 square miles with probably wide extensions under heavy cover. The outcrops along the main river and tributary streams have been estimated as 175 miles in length.

Along these exposures the overburden varies on some stretches it is reported as too heavy to allow of commercial development, but on others it is comparatively light or easily removable, consisting of shales and sandstones. It is estimated that about 20 per cent of the exposures are of commercial interest owing to the comparative cheapness with which the bituminous sand can be won, and that systematic boring would no doubt disclose many other localities where overburden was sufficiently light to allow of development at reasonable cost.

Analysis of seventy-two samples made in the Department of Mines gives the bituminous content of the sands as from 12 to 17 per cent.

General W. Lindsay claims to have a process for extraction of the crude oil and other values. The results of the General's proposed activities are awaited with interest. The total known deposits have been estimated to hold about 30,000 million barrels of oil.

A sample of the bituminous sands recently displayed in New York at the American Exhibition of Chemical Industries, in the booth of the Canadian Pacific Railway Co., attracted an immense amount of attention. This sample was subsequently treated by two processes and gave a return of over 20 per cent of crude per ton of raw material.—*Agricultural and Industrial Progress in Canada*, Montreal, vol. 2, No. 12, December, 1920, p. 27.

Low-Temperature Coking of Utah Coals

A Summarized Description of Laboratory Investigations Made to Determine the Coking Property of a Series of Utah Coals—Analysis of Coals Tested—
Apparatus Used—Tabulated Results Obtained

BY OSBORN MONNETT

COKING processes fall into two general classes—high-temperature processes and low-temperature processes. In the first class coal is carbonized at temperature of from 900 to 1,200 deg. C., producing a coke with very low volatile content which is correspondingly difficult to ignite. The low-temperature process, now being given considerable attention by engineers, proposes to carbonize coal at temperatures of 450 to 600 deg. C. and produce a coke with higher volatile content, which can be more readily ignited.

Of the commercial plants in operation in the United States at the present time practically all are high-temperature processes. These include beehive ovens, in which the byproducts are not recovered; byproduct ovens of the Koppers or Semet-Solvay type, and the ordinary gas retorts for the manufacture of illuminating gas. When a ton of coal is carbonized in a byproduct oven at a temperature of 900 to 1,200 deg. C. the following products are obtained: 1,100 to 1,400 lb. of coke; 10,000 to 12,000 cu.ft. of gas (measured at 60 deg. F. and 30 in. pressure); 8 to 12 gal. of tar and 20 to 24 lb. of ammonia as ammonium sulphate.

To supply the present needs of Salt Lake City for domestic fuel only 210,000 tons of coke would have to be produced annually. This would necessitate the carbonization of about 350,000 tons of coal and would produce nearly 4,000,000,000 cu.ft. of gas, 3,500,000 gal. of tar and 4,000 tons of ammonium sulphate.

High-temperature coke usually contains only about 2 per cent of volatile matter and for this reason is difficult to ignite or control in a domestic stove or furnace. However, with proper methods such coke can be made to give good results. Where a supply is available the public should be urged to buy coke and educated in the proper methods of burning it. There are about 15,000 tons of gas coke available yearly in Salt Lake City, most of which is shipped out of the state. A small number of Salt Lake residents have burned this coke for years with satisfactory results. Steps should be taken to bring about the consumption of all this coke in Salt Lake City.

LOW-TEMPERATURE COKE

During the past ten years increasing attention has been given to the possibilities of low-temperature carbonization. A low-temperature coke is one containing sufficient volatile matter to make a fuel which ignites and burns readily. When coal is carbonized at temperatures of 450 to 600 deg. C., coke and byproducts differing in nature and amount from those produced

by the high-temperature process are obtained. The coke still contains from 8 to 15 per cent of volatile matter and is more suitable to domestic use. It ignites readily, somewhat similar to semi-bituminous coal and burns without smoke. The smoke-producing constituents have been decomposed and driven off during the carbonization process.

The tar produced in such a process is a thin fluid better called an oil. It is produced in twice the quantity given in high-temperature carbonization. It contains considerable quantities of motor fuel, burning and lubricating oils, a small amount of pitch and 20 to 40 per cent cresols and other phenols. The gas is produced in smaller amount but is of high calorific value. One ton of coal carbonized at a temperature of about 450 to 600 deg. C. will give 1,300 to 1,500 lb. of coke; 2,000 to 7,000 cu.ft. of gas; 20 to 30 gal. of tar, and 2 to 8 lb. of ammonium sulphate.

DISPOSAL OF BYPRODUCTS

Disposal of the gas produced offers the most difficult problem in the operation of a high-temperature carbonizing plant at Salt Lake City. Tar and ammonia can be sold at points some distance away. Gas must be consumed as soon as produced and sold in or near the city.

As heretofore shown, a plant of sufficient size to supply a high-temperature coke to domestic consumers in the city would produce nearly 4,000,000,000 cu.ft. of gas. Salt Lake City uses at present about 420,000,000 cu.ft. of gas, or about one-tenth of the amount produced by a plant of the above size. Part of this gas might be used in carbonizing the coal, but disposal of the remainder would be a difficult matter necessitating the selling of the gas at a low rate for industrial and domestic purposes and holding down the production of coke for many years while the demand for gas was being built up.

Low-temperature carbonization produces about one-third as much gas, practically all of which can be used in the carbonization process itself. In this respect low-temperature carbonization seems the more feasible.

LOW-TEMPERATURE COKING INVESTIGATION

In view of the importance of this subject and the fact that little was known of the behavior of Utah coals in low-temperature processes, it was thought advisable to make a rather detailed study of the coking properties of Utah coals and inquire into the state of the art of low-temperature carbonization as represented by various investigators. Results obtained together with an outline of the methods used in the investigation will be set down.

Sunnyside coal is the only known Utah coal of good

EDITOR'S NOTE: This article forms a part of the Bureau of Mines report (June, 1920) on its smoke-abatement investigation in Salt Lake City, as studied in co-operation with that city and with the University of Utah. Published by permission of the Director, Bureau of Mines.

coking value. A large quantity of this coal is coked in beehive ovens at Sunnyside. This coke is used for metallurgical purposes in Utah and on the Pacific Coast. Sunnyside makes an exceedingly good grade of coke which compares favorably with the best coking coals of the East. Castle Gate coal was at one time used in the beehive ovens, but produces a coke inferior to Sunnyside.

COALS TESTED

Fifteen 30-lb. samples of coal were collected from the yards of Salt Lake City. These include practically all the different varieties of coal on the market. Samples of these coals were sent to Pittsburgh for complete analysis. A rapid survey of the coking power of these coals was made, using the 20-g. byproduct apparatus shown in Fig. 1A. Ten of those showing the best performance were shipped to Chicago for testing in the 8-lb. apparatus shown in Fig. 1B.

Description of these coals is set down in Table I. Proximate and ultimate analyses and calorific values appear in Table II.

DESCRIPTION OF APPARATUS AND METHODS

Apparatus for Testing 20-g. Sample. This is essentially that described in "Methods of the United States Steel Corporation for the Commercial Sampling and Analysis of Coal, Coke and Byproducts." An electric furnace was used instead of the gas furnace as used by the Steel Corporation. This was found to give a more easily regulated temperature and to be much simpler to operate. The methods of the Steel Corporation call for a progressive distillation process, in which one burner at a time is lighted. This can be accomplished with an electric furnace by surrounding the tube containing the coal with a metal water jacket which is moved backwards at intervals.

Referring to Fig. 1A: An electric furnace (1) sup-

NOTE: A—Carbonized at 540 deg. C. B—Carbonized at 700 deg. C.

plies heat for carbonizing the coal contained in a glass combustion tube. The products of distillation pass through a tar filter packed with absorbent cotton heated by the steam bath (2). The Geissler bulb (3) contains normal sulphuric acid for absorbing the ammonia, a U-tube containing calcium chloride absorbs water, Geissler tube (4) contains strong KOH solution which absorbs H₂S and CO₂, the tubes (5) and (6) contain paraffine oil for absorption of benzene. The gas is measured in the aspirator bottle (7). The furnace was tilted at an angle of 15 deg. to the horizontal to avoid cracking of the tar. Results give the yield of coke, tar, gas, ammonia and crude benzene.

The apparatus was designed to run in comparison with regular coke plant operation until a correlation was obtained. Results are naturally somewhat relative. A maximum temperature of 900 deg. C. is called for in the Steel Corporation methods. The apparatus affords a rapid means of determining in a general way the suitability of coals for byproduct coking.

Tests were made with this apparatus at temperatures of 700 deg. C. and 550 deg. C. It was found impossible

to use higher temperatures than 700 deg. C. due to the fusibility of the glass tubes employed. In the tests at 700 deg. C. the progressive distillation method was employed, making use of the sliding water jacket previously described. In the tests at 550 deg. C. the entire tube was gradually heated to the desired temperature.

Results are tabulated in Table III. The low tar yields obtained at 700 deg. C. with some of the coals are not to be taken as indicative of the actual performance of the coal. In the tests at 700 deg. C., the furnace was not tipped at an angle with the horizontal as in later tests and the tar in some cases ran back in the tube and was decomposed.

APPARATUS FOR CARBONIZING 8-LB. SAMPLES

This apparatus shown in Fig. 1-B is modeled after the apparatus used by Prof. S. W. Parr of the University of Illinois.¹

¹Use of the apparatus was obtained through the courtesy of the Commercial Testing & Engineering Co., 1785 Old Colony Bldg., Chicago, Ill. Our thanks are due to W. D. Langtry, president of the company, for making possible use of the apparatus and to J. F. Kohout, chemical engineer, for valuable assistance and advice in making the tests.

TABLE IV. RESULTS OF LOW-TEMPERATURE CARBONIZATION

Tests run on 8 lb. of coal. Maximum temperature 1,000 deg. F.

FIG. COKING APPARATUS, 8-LB. SAMPLE, SET UP IN THE LABORATORY

FIG. 1. DIAGRAMS OF EQUIPMENT FOR HYPRODUCT COKING TEST

A. Apparatus for carbonizing 20-g. samples. B. Apparatus for carbonizing 8-lb. sample.

The coal is carbonized in a vertical retort of 3½-in. pipe (1). This is surrounded by firebrick jacket (2) and heated by ring burner (11). The flame of the burner is so regulated that it surrounds the pipe from bot-

tom to top. Tar condensed in the air condenser (13) is caught in the trap (3). Condensate from the water condenser (4) is caught in the separatory funnel (12). The gas then passes through the scrubbers (5) and (6), through the H₂S purifier (7) and is measured in the meter (9). Samples of gas are taken for analysis by means of the sampling tube (10). The rotary pump (8) serves to regulate the pressure, which is measured by a manometer.

In the tests on Utah coals, the maximum temperature of carbonization was 1,000 deg. F. This temperature was reached in about two hours and maintained for two hours longer. Tar and gas evolution was as a rule practically complete after the first two hours.

Results are tabulated in Table IV. Analyses of the coke are given in Table V. The sample of Sunnyside coal used in coking tests was a different sample from the one analyzed. In figuring the moisture and ash free values for the byproduct yields on this coal an approximation was used.

CHARACTER OF COKE PRODUCED

Results show that while a number of the coals have a marked tendency to coke, Sunnyside is the only coal which can be called a good coking coal. Castle Gate makes a fair grade of coke. A mixture of one-half standard and one-half Sunnyside made a good coke.

A number of investigators are working on modified methods of coking and claim to have made satisfactory coke from coals not known as strictly coking coals. More research work is necessary before it can be established definitely how far such processes will go in making satisfactory coke from non-coking coals. In the meantime the matter must be considered as in the experimental stages and as something to be worked out in the future.

Legal Notes

BY WELLINGTON GUSTIN

Where Trade Custom Becomes Part of Contract

The Colfax Gin Co., of Colfax, Ga., sued for the purchase price of a carload of cotton seed sold by it to the Buckeye Cotton Oil Co., contending that it was entitled to recover for the amount of seed as shown by the weights when loaded at Colfax, the point of shipment. It was provided by the contract of purchase that the defendant was to pay for the cotton seed a stated price per ton "f.o.b. Colfax, Ga." The Buckeye company contended that it should pay only for the amount of seed received at the point of destination, and alleged that "in the cottonseed oil business it is a custom to settle and pay for all shipments of cotton seed at mill weights—that is, the weight at time and place of delivery—and said custom is of such universal practice that it becomes a part of all contracts for shipment and purchase in carload lots of cotton seed, and was a part of the contract in this case."

The trial court allowed the Buckeye company thus to amend its answer. But the Colfax company objected, contending that "the contract sued on was not ambiguous and that the Buckeye company could not set up and prove in defense of the suit the alleged custom which sought to vary the terms of the contract," and that "f.o.b. Colfax," as contained in the contract, meant that title to the seed passed to the buyer as soon as loaded and that any loss in weights would fall on the purchaser.

On this controversy the Court of Appeals of Georgia held that while a custom or usage of trade cannot be set up to vary a written unambiguous contract whose terms are incompatible therewith, the words and letters "f.o.b. Colfax," as contained in the contract of purchase, would ordinarily mean merely "free on board" at that point, and that the purchaser was to be responsible for the cost of shipment, and the contract as made was therefore silent as to what weights were to govern in the settlement for the cotton seed. Therefore the amendment allowed the Buckeye company was proper. (75 Am. S.R., 73.) And while, in the absence of an agreement to the contrary, delivery of freight to a common carrier is regarded as delivery to the consignee and any loss or damage to the goods while in transit would fall on the purchaser, this rule may be varied by agreement (80 S.E., 863); and if at the time the contract of purchase in the instant case was made there existed such a custom as that alleged by the Buckeye company which was of such universal practice that it became by implication a part of the contract, this would amount to such an agreement as would prevent the application of the general rule above stated.

The defendant debtor herein sent a check to plaintiff creditor for the amount which the debtor claimed was due. The creditor held this check and the debtor contended this was accord and satisfaction. On the point the court said that in the absence of an agreement to the contrary, a bank check thus tendered as in full payment is not such until it is itself paid, under the Georgia statute. Thus, where a claim is unliquidated because of a bona fide dispute as to the amount due,

and the debtor sends a check to the creditor for the amount which the debtor claims is due, but for less than the amount claimed by the creditor, with and upon the express condition written upon the check that it is to be in full settlement of the disputed claim, it is only where the creditor either has agreed to accept or after the tender actually does accept such a check as being of itself in full settlement of the unliquidated demand that the mere retention of such an unpaid check can be set up as an accord and satisfaction.

The evidence in this case being in conflict as to whether or not there had been an express agreement that the check itself was to be accepted as payment, the trial court erred in directing a verdict for the Colfax company and the judgment was therefore reversed.

When Broker Earns His Commission

The United States Circuit Court of Appeals, Second Circuit, reversed the District Court for the Southern District of New York in the action brought by Francis H. Baldwin against Jardine, Matheson & Co., in which judgment was given the defendant. Baldwin sued to recover commissions in procuring a purchaser for 10,000 base boxes of tin plate. His commission was to be the sum obtained in excess of \$8.50 per base box. After hearing the evidence the court directed a verdict for defendant, and plaintiff appealed. The question argued on appeal was whether a jury question was presented which required its submission to the jury.

The plaintiff alleged that he secured a buyer, the American Trading Co., for the 10,000 base boxes of tin plate at a price of \$9.25 per base box; that Jardine, Matheson & Co., Ltd., agreed to and accepted the terms of the sale, payment to be made upon receipt of the tin plate at the dock of the American Trading Co. at Yokohama, Japan. It was further alleged that, in violation of the agreement made with the American Trading Co., the defendant refused to make delivery of the boxes of tin plate, or to pay the commission.

On the question presented on appeal the court said that in an action by a broker for commission on a sale of merchandise, whether the agent who made the purchase had authority, or whether, if not, his action was ratified by his principal, are both questions for determination by the jury.

The plaintiff was entitled to succeed, irrespective of whether the defendant acted in good or bad faith in endeavoring to deprive him of his commission. There is no difference between failure to perform because of bad faith or inability. It is sufficient to entitle a broker to his compensation if it appears from the evidence that a sale was effected through his agency in procuring a buyer. If his communications with the purchaser have been the means of bringing the purchaser and principal together and the sale is agreed upon in consequence thereof, his right to compensation is perfect. The broker is not entitled to compensation for unsuccessful efforts to make a sale unless the failure has been caused by the fault of his principal. When he has been allowed a reasonable time to effect a sale, and has failed, and the principal has in good faith terminated the agency and effected the sale through his own efforts, the latter is not liable for commissions.

Again it was said that a court may direct a verdict only where the evidence is undisputed and so plainly preponderant on one side that it practically becomes conclusive, so that reasonable minds could not differ as to the conclusions to be drawn from the testimony.

Adsorption by Silica Gel*—III

Physical Properties Affecting Plant Design for Solvent Recovery, Drying Air and Industrial Vapor Recovery — Vertical Cylindrical and Bed Type Absorbers — Typical Plant Testing Records†

BY E. B. MILLER

SILICA gel is prepared under carefully standardized conditions and when dried and activated has a moisture content of 5 to 7 per cent. It is a semi-transparent, glassy, brittle, highly porous substance. Its hardness is from 4.5 to 5.5 on the mineral scale and it suffers but slight abrasion with ordinary handling. If, when activated, it comes in contact with water or other liquid rapid adsorption takes place with evolution of heat and the granules are shattered.

The pores are ultramicroscopic and neither the structure nor adsorptive properties are measurably altered by pulverizing the gel to pass 200 mesh or heating

1 in. in diameter on 2-in. centers passing through the gel bed, which is 26 in. deep supported on a screen about the middle of the cylinder. Hot gases or cooling air or water may be passed vertically through the tubes and the gas for adsorption enters and leaves by side outlets below and above the gel bed, which contains 250 lb. of 8 to 14 mesh gel. Most of the practical work on SO_2 adsorption and recovery was done with this absorber.

The first absorber did not have welded tubes, and to overcome difficulties in keeping it tight and getting even distribution of the heat the second absorber was built.

Figs. 15 to 17 show the second bed type absorber plant. The absorber A is a rectangular steel box 3 ft. 9 in. x 3 ft. 6 in. x 2 ft. 10 in. high with a 420-lb. gel bed 9.75 sq.ft. x 13 in. deep, supported on a perforated metal screen. Through the gel bed passes a series of horizontal 1-in. tubes on 2-in. centers. These tubes are welded to the tube sheets, which are inflosed on both sides of the absorber by flue boxes so that combustion gases, air, or cold water can be run through the tubes to heat or cool the gel.

The plant as shown is arranged for drying air. The air enters through an orifice meter B, Figs. 15 and 17, passes into the absorber A at the lower right corner and up through the cool gel bed, where it is deprived of its moisture, thence by the upper left corner of the absorber through valve 1 to a Roots exhauster C and out by valve 2 for use as desired.

If it is desired to continuously make a high extraction of the vapor a second absorber should be connected in series when the effluent from absorber A indicates it is reaching the break-point and absorber A is continued in circuit until the gel is saturated. The air is then cut off at damper 1 and the gel is dried or reactivated by heating and sweeping hot air through it. The heating or evacuating cycle is shown in Fig. 15. Combustion gas or hot blast is admitted alternately by the dampers 2 and 3, passing through the tubes in the gel and out by dampers 5 and 6 to the heat exchanger D. Air is admitted to the heat exchanger on the lower right side, is heated and passes through valve 5 to the bottom inlet of the absorber, thence through the gel to the blower

FIG. 17. RESISTANCE TO VAPOR AND GAS PASSAGE

gradually to 650 deg. C. Its internal volume is indicated by the fact that 1 g. of gel will adsorb 0.41 c.c. of water.

Gel sized from 8 to 14 mesh and containing 7 per cent water weighs 44 lb. per cu.ft.

The resistance of an 8 to 14 mesh gel bed to the passage of air or vapor through it is an important practical factor. Laboratory and plant results are given in Fig. 13. Plant absorbers have staggered heating flues in the bed which modify the laboratory test conditions.

During adsorption the heat of condensation is liberated and, despite radiation losses, a rise of as much as 25 deg. C. in gel temperature has been noted when there was no attempt to cool the gel by ventilation or water jacketing during the adsorption cycle.

Gel can be used either in the granular or pulverized form and the work with semi-commercial scale bed type absorbers for granular gel and that now under way with pulverized gel will now be described.

The first plant absorber is shown in Fig. 14. It is a vertical cylinder with vertical heating and cooling tubes

FIG. 14. VERTICAL CYLINDRICAL ABSORBER

*Paper presented before the American Institute of Chemical Engineers, Montreal, June 28, 1920.

†For Parts I and II see CHEM. & MET. ENG., vol. 23, Nos. 21 and 25, Dec. 15 and 22, 1920, pp. 1,155 and 1,219.

FIG. 15. BED TYPE ABSORBER AND CONDENSER PLANT

and to waste through the valve 2, carrying with it the released moisture.

When the gel is dried cooling may be hastened, if necessary, to prepare it for the next absorption cycle by blowing cold air from inlet valve 3 through valve 4 and dampers 9 and 3 through the absorber tubes and out by damper 5. Water spray is used with this cooling

FIG. 16. ABSORBER BOX AND CONNECTIONS

air at the start and the tubes and flue boxes are flooded with water when the temperature is below the boiling point. The next cycle can be started when the temperature has been reduced to 75 deg. C., as the air being dried will assist in the cooling and the jacketing water will lower the gel to a moderate temperature before the break-point is reached.

The air drying tests were made in this absorber.

A third type of bed absorber using granular or unsized gel flowing slowly through a louvered or screened compartment, thus making a continuous absorber, is under consideration.

For continuous operation and uniform product three fixed bed type absorbers are needed so that a second one can be put in circuit a safe

interval before the first one reaches its break-point while the third one is on its heating and cooling cycle.

In the pulverized gel absorber the activated dust is fed into the gas stream discharging into a dust filter, adsorption taking place in the duct and filter bags.

This method is attractive from several points of view.

It requires only standard equipment such as is regularly used in feeding powdered coal and in dust separating in metallurgical plants.

It seems clear that a smaller quantity of gel would be required for a given duty than with a bed type absorber, because there is no time lost in heating and cooling an absorber nor is there any idle gel in an absorber bed.

The heat is economically applied since the heater is always hot, as against the intermittent heating and cooling of the bed absorber.

Preliminary tests in the laboratory using 80 and 200 mesh gel in a current of air with 2 to 6 grains of moisture per cu.ft. reduced the effluent in one stage to from 1.0 to 1.3 grains. In the above tests the time of contact between air and gel did not exceed four seconds, which later experiments have shown to be inadequate. Apparatus now under construction will permit longer and better contact.

Fig. 18 is a suggested flow diagram for a pulverized gel absorption plant.

EXPERIMENTAL PLANT RESULTS

A large number of tests were made with the No. 1 absorber on the adsorption and recovery of sulphur dioxide from air mixtures ranging in concentration from 2.5 to 8.75 per cent by volume. The data are too bulky to include in this paper.

Fig. 19 gives the results of a typical run on adsorption from an 8.75 per cent mixture. The mean temperature of the gel at the end of the run was about 40 deg. C. and it adsorbed 17 lb. of sulphur dioxide, or 6.8 per cent of its own weight.

FIG. 17. OUTLET AIR VENT PIPING

below the moisture content in any continuous run of a Gayley dry blast plant of which we have record.

Fig. 22 is of a run at 225 cu.ft. per minute rate when the humidity averaged about 4.5 grains per cu.ft. and the outlet air reached the 0.7 grain end point in four hours, forty-five minutes, finally rising above this point

FIG. 22. DRYING AIR AT A RATE OF 225 CU.FT.

in five and one-half hours. When atmospheric humidity was below 2 grains runs of six and seven hours have been made without reaching the 0.7 grain end point.

INDUSTRIAL APPLICATIONS

It will have been seen from the preceding discussion that silica gel is adapted to recovering the vapors of all liquids.

This property may be applied to the following among many other practical commercial problems:

Drying air: Air conditioning; dry-air blast for furnaces.

Gasoline recovery: From gas wells; casinghead gases; losses from storage tanks; losses in oil refineries.

Solvent recovery: All industries using volatile solvents.

Recovering industrial vapors: Notably sulphur dioxide and oxides of nitrogen.

Selective separation of mixed gases.

A more specific list of possible applications is not within the limits of the present paper.

While further work remains to be done to reduce the above applications to commercial practice, we feel that the theoretical and scientific aspects of the problem have been completely solved, and that to make commercial application requires only the perfection of mechanical equipment, which presents no serious engineering difficulties.

The progress already made in this direction, as indicated by the results of the experiments here recorded and other experimental operations now under way, conclusively establish the practicability of silica gel as a means of recovering the various vapors mentioned above.

ACKNOWLEDGMENTS

The work necessary for the preparation of this paper was divided into three general groups, and intrusted to members of our research and engineering staffs as follows:

Theory, to Walter A. Patrick; laboratory results, to Benjamin F. Lovelace; experimental plant, to Edwin C. Holden.

British Progress in Chemistry*

BY WILLIAM MACNAB

THE war has shown up very clearly many of the weaknesses in our technical educational system. On the other hand, it has brought many professors into close association with technical men and processes, and this no doubt has produced a greater appreciation on their part of the necessity of providing more technical instruction for students who purpose to enter chemical industry. Many of the drawings and reports to be issued should prove of much assistance to universities and teaching institutions in carrying out technical instruction, by showing good methods of applying scientific data to industrial questions, and, by presenting concrete examples, thus vitalize to many students the apparently less interesting field of thermochemistry and other branches of physical chemistry.

The resources and ingenuity displayed in meeting the complicated problems arising from the necessity of devising means of protection against gas attacks and the production of gases for attacks show that the country possesses ample chemical ability to meet any calls which may be made.

CLOSER CO-OPERATION ESSENTIAL

But to meet the chemical industrial competition closer co-operation between the more strictly theoretical and technical workers is essential, and above all a class of business and financial men must be developed whose education has been sufficiently broad to enable them to realize the sure foundations on which scientific conclusions rest, and to trust their scientific and technical advisers.

In this country there has been too little mutual trust and appreciation of each other, and it must be the serious endeavor of all concerned to develop such sure methods of working out new processes in all details, and clearly presenting the results, that the business man may have a well-defined picture of the advantages to be gained and the cost to be incurred, in so far as the factory is concerned.

CHEMICAL ENTERPRISE SUFFERS FROM IGNORANCE

Chemical enterprise has suffered much from the comparative ignorance of many who entered upon its difficult path. On the one hand, the air of mystery which often surrounds it to the lay mind leads to expectations of almost magical results and exaggerated hopes which are rarely fulfilled.

The business man is often not entirely to blame, for the chemical projects have often been presented to him in a very insufficiently considered manner, so that the attractive points—although no doubt truly put forward—were not sufficiently counterbalanced by a well-reasoned statement of all the sides of the question. Hence disappointment and loss of faith, or, at any rate, considerable skepticism in regard to future chemical projects.

On the other hand, if a non-scientific man has the final decision in regard to a chemical process, his lack of understanding of his technical staff and of faith in their requests, which may go against his so-called common sense, may be as prejudicial as the unreasoning hope before referred to. Unfortunately this trouble

*From the introduction to Ministry of Munitions' publication "Preliminary Studies for H. M. Factory, Gretna, and Study for an Installation of Phosgene Manufacture."

arises from the lack of general scientific knowledge among all classes of society and the failure to appreciate what scientific work stands for, as well as reluctance to make use of the scientific information which is available.

ATTITUDE TOWARD CHEMICAL INDUSTRY MUST BE ALTERED

But if we are to hold our own in the world competition, the attitude to chemical industry must be altered very considerably. Greater knowledge on the part of those directing chemical work and the substitution of the rule-of-thumb men (who are often in complete charge of complicated processes) by intelligent chemists who will make it possible for real progress to be made are among the more obvious reforms to be introduced.

Shrewd common sense and good powers of observation have enabled some of our non-scientific owners or managers of chemical factories to achieve sometimes a considerable amount of success, which has developed in them a corresponding contempt for, and distrust of, scientific control.

It must be admitted that when a young chemist has been taken on in such a works the results frequently have been unsatisfactory, due to lack of knowledge on both sides. Truly Solomon was right when he insisted: "Get wisdom, get understanding." To get it, however, implies hard work and a certain amount of modesty which does not count too much on the influence of heredity.

PROBLEMS OF YOUNG CHEMISTS IN INDUSTRY

Our teaching institutions do not turn out industrial chemists ready to step into a works and successfully control processes straight away, nor perhaps is it to be expected or desirable that they should, for after all, works experience and the controlling of men can only be learned in a works. Sometimes the young chemist's position in a works run on rule-of-thumb principles is very trying. His inexperience may lead him into trouble, and his mistakes will cause unholy joy to the rule-of-thumb foreman and anger or dissatisfaction to the uncomprehending employer, with the probable result that he is confined entirely to the laboratory or even dismissed, and scientific control has thus apparently been found to be a fraud.

Or he may develop an unjustified contempt for the "rough and ready" people with whom he has to work, forgetting that the ability to produce something, although unable scientifically to understand and explain the process, is worth more in a works than scientific comprehension of the process along with lack of technical ability to carry it out, or knowledge of pitfalls, should a change be undertaken in the existing practice.

It seems ridiculous to have to plead for the full and proper use of chemists in chemical works, but to those acquainted with the smaller works, and even some of the larger ones, it is known that the necessity exists.

The difficulty would be largely solved if men with good chemical training were in charge of chemical works, for then they could see to the works' training of the young chemists who came under them and prevent them from making rash experiments and, at the same time, utilize to the full extent any knowledge or initiative which they might possess. Above all, such a manager would not be jealous of the chemist.

Repeated opportunities of visiting during the war

most of the French factories employed in making explosives and allied chemical products filled one with great admiration for the work accomplished and the developments carried out, and it is evident that a chemical industrial renaissance has taken place in France and manifestly they intend to develop chemical manufacture which the war has shown they can carry on well.

In this country there has also been great chemical development and a new spirit of scientific control and efficiency has been made known widely. Magnificent results have been achieved, but not through rule-of-thumb methods, which one would fain hope were buried forever.

DEVELOPMENT ON SCIENTIFIC LINES URGED

It has been abundantly shown that the chemical knowledge and ability in this country, when adequately directed, can hold its own with that of any other land, but the stimulus of the common aim of quantity of output and excellence of production, generated by the war, must not be allowed to die out. Every endeavor should be made by professors and students, technical and business men interested in chemical manufactures, as well as by the government, to get to understand better the aims and requirements of one another, and co-operate in remedying any weaknesses in our system and in developing chemical industry on sound scientific lines.

Progress means change, and the chemical manufacturer should be prepared for having one process ousted by a newer and better way of working, and should reckon with the necessity of scrapping plant from time to time if he is going to keep pace with improvements.

PROGRESSIVE SPIRIT NECESSARY

Sometimes chemical enterprise is deprecated on the ground that no sooner is one method established than a new process threatens to supersede it and therefore there is no certainty of permanence. A truly progressive spirit is necessary and the mental laziness which tends to condemn new ideas because they upset a smoothly running process must be replaced by greater alacrity to undertake new methods with all the attendant trouble, otherwise a back seat will soon be taken by the firm or nation which will not wake up and keep awake. More friendly and intelligent co-operation among masters and staff and ordinary workers will do much to make progress easier. Already there are indications of sounder and humaner ideas coming to the surface, and seeing we have all to spend the greater part of our life working in some capacity or other it is surely worth while endeavoring to make the work as interesting as possible.

COMPETITION MUST BE MET

All the chemical manufacturers of the world have been greatly developed and stimulated by the war and competition will be keener than ever on all sides. The old rule-of-thumb practice which prevailed in so many of our chemical factories must go and be replaced through scientific control of every stage of the process.

The necessary data and information are available in the country and there are plenty of chemists with brains who can carry on and develop the good work begun.

The young chemist who starts work in a chemical factory finds himself confronted with plant instead of apparatus, much of which involves mechanical devices.

of various kinds, pumps and blow casks for moving liquids, mechanism and compressed air for agitating liquids, various methods of applying heat, etc. He should make it his business to get first-hand knowledge of the way each part of the plant acts and a thorough understanding of the principles on which it works and is constructed.

To do this he should take his coat off when a breakdown or stoppage occurs and see for himself what has been the cause, and learn and help to put matters right. Only in this way can he develop that knowledge of the capacities of a plant and sympathy with it which will enable the best results to be obtained.

A plant should be treated well and considerately, and its legitimate work capacity not overtaxed. Careful attention to its smooth running and maintenance in good condition will be richly repaid in steady and uniform output.

MANUAL WORK BY THE CHEMIST SOMETIMES NECESSARY AND EXPEDIENT

There is nothing *infra dig.* in a highly trained scientific man doing the manual work involved in any of the processes under his control. Thereby he acquires a greater sympathy with and understanding of the men who have to do the regular manual work, which enables more just judgments to be formed as to what constitutes a fair day's work, and develops a mutual respect between chemist and workman.

One does not rejoice in dirty work *per se*, but, as a means to an end—viz., the intelligent understanding of plant and process—it should be cheerfully undertaken when occasion arises. Also the more carefully a plant is controlled the fewer interruptions and occasions for rough work will arise.

In the laboratory the chemist is trained to work quantitatively in so far as the main constituent he is preparing or substance he is analyzing is concerned, but he is seldom required to account for the quantity of reagents he employs or the amount of heating or cooling and water for washing he utilizes to effect his end.

PROBLEMS OF THE PLANT CHEMIST

In the factory these questions become of first-rate importance and must be carefully attended to. Every part of the process should be quantitative, and thereby it acquires added interest. The plant should be carefully calibrated, so that accurate measurements and weights of all materials used can be ascertained, and frequent stock taken in order that yields and losses may be accurately known and any departure from the normal at once detected. Let the chemist keep prominently before him in large figures the losses, so that they may be a constant incentive to greater efforts to bring them down to the irreducible minimum.

In order that the chemist in charge of a process may work it to the greatest advantage he must be provided with all available knowledge on the subject, and must be encouraged to investigate by means of laboratory and plant experiments all obscure points and losses. To this end he should be taken as far as possible into the confidence of his employer in regard to costs, so that he may realize the necessity of economy in all directions and be able to measure in one of the terms of industrial success—viz., money—the results of modifications and improvements which he may introduce.

Intelligent and sympathetic co-operation among

those in charge of different departments is necessary if the greatest efficiency is to be obtained. Some works have followed the opposite practice and kept the sections in water-tight compartments. Profits have no doubt been made under such systems, but not so great as when the heads and their assistants have opportunity to discuss their several problems together and help one another by trying to work into one another's hands. Without this co-operation the nation loses greatly both in material and the improvements which are sure to flow from the brightening of intellects by free discussion together.

It sometimes happens that owing to exceptional circumstances profits are made alongside of great waste of material. Such a state of affairs is a national misfortune and, apart from the loss of material, which is also likely to be a nuisance to other people, it is demoralizing and engenders a careless, unscientific spirit in those conducting the operations. Preventable waste of any kind should be considered a sin against mankind.

INTEREST BY THE EMPLOYEE AN AID TO BETTER RESULTS

One of the most powerful aids to success would be the intelligent and loyal co-operation between employer and employee with the object of getting the best results from the process being worked. Interest in the work in hand leads to better work being done, and one tendency of the time seems to be a revolt of the individual from being regarded as a "hand" or human machine, and a demand that some of the necessary monotony of the daily task should be brightened by learning as much as possible of the meaning of what is being done and the ideals to be striven for.

The work of a chemist on a plant, although much more varied, can become monotonous too, unless he can see beyond the immediate daily round, and have the interest and stimulus of knowing the profit or loss on his operations, while his attention should be concentrated on the production of the manufactured article at the lowest cost and greatest efficiency.

British Cast Iron Research Association

Good progress is being made with the organization of the British Cast Iron Research Association, which has abandoned the somewhat cumbersome title of the British Gray and Malleable Cast Iron Industries Research Association in favor of the shorter one. Articles of association have been drawn up and approved by the council. Lord Weir of Eastwood has accepted the office of president, H. B. Weekes, F.I.C. (Vickers, Ltd., Barrow), has been appointed chairman of the council, and three additional vice-presidents have been elected.

The basis of subscription of ordinary members has been fixed according to the number of persons employed in the iron founding departments of the businesses. For gray iron foundries the rates are five guineas per annum for less than twenty-five employees, ten guineas for between twenty-five and fifty, and an extra five guineas for every fifty additional employees or fraction thereof. For malleable iron foundries, five guineas per annum for under twenty-five employees, and above that number the rates are those for gray iron foundries increased by 25 per cent. Pattern-makers, clerks, etc., are not to be included in the count of employees. Many of the largest firms in the industries are supporting the association, and ample financial assistance is promised.
